FIG. 4—SMALL MOTOR CLAMPED WITH BEVELLED WASHERS

In modern plants the practice of using structural steel for supporting motors is every day becoming more popular. In some shops wood construction, and, in fact, any construction that is combustible, is not permitted.

Structural steel is used instead and provides a permanent, rigid, and fireproof frame for the motor platforms. Small motors can be conveniently mounted on a couple of channels, as suggested in Fig. 4. The holding-down bolts of the motor pass through holes in the channel flanges and are held therein by nuts turned on at the lower ends of the bolts. Inasmuch as the sloping surfaces of channels and I-beams always slant with a 6 to 1 pitch, it is necessary to insert so-called beveled washers between the holding-down bolt nut and the flange face, as shown in Fig. 5, so that the nut will have a horizontal surface upon which to slide. Fig. 7, in connection with Table I, shows dimensions of beveled washers for use with I-beams and channels that have been found satisfactory in practice. It is not usually possible, so far as the writer is aware, to obtain these beveled washers on the open market. They can sometimes be secured from the structural steel companies, but if many are to be used it will pay any concern to make a pattern like that shown in Fig. 6 and have the washers cast at the nearest foundry. It will be noted that in the pattern of Fig. 6 a deep groove is cut between adjacent washers. A strip of a half dozen or more washers is cast from one pattern and then the washers can be broken off along the grooves as they are required.

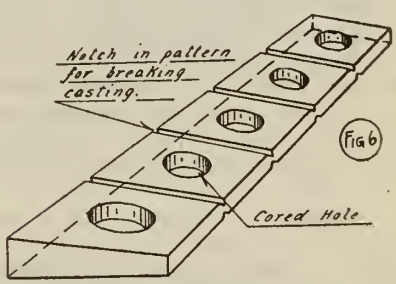

FIG. 6—METHOD OF CASTING CHANNEL WASHERS

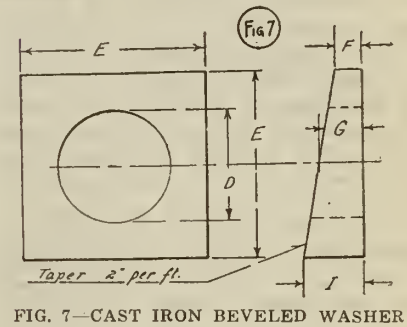

FIG. 7—CAST IRON BEVELED WASHER

With larger motors, it is not feasible or desirable to bolt them directly to the flanges of steel sections as shown in Fig. 4. The disadvantage of this Fig. 4 method is that the holes must be drilled accurately in the channel or I-beam

flanges for the accommodation of the holding-down bolts, and furthermore, that after the holes have been drilled only one position of the motor is possible. The arrangement of Figs. 8 and 9, wherein cast iron channel washers, Fig. 10, are used for clamping the structural steel members together, eliminates both of these disadvantages. No drilling is required in the channels that comprise the supporting frame, and the character of the construction is such that the motor can be readily shifted along the two channels upon which it rests, and these two channels can in turn be shifted along the members upon which they rest, so that the motor can be readily aligned with the pulley which it is to drive.

As suggested in Figs. 8 and 9, two channels are always used to form a supporting beam where the channel washers are utilized. The channel washer has two functions. The first is that it provides a means of clamping the two channels that fit into it to some other member, and the second function is that it maintains these two channels at a given distance from one another. The protection, G, in Fig. 10, maintains the channels at a given distance apart. It is seldom possible to obtain these channel washers on the market, and for this reason Table II is given to show some dimensions that have proven satisfactory in practice. These channel washers can be used for other size sections than those shown in the first

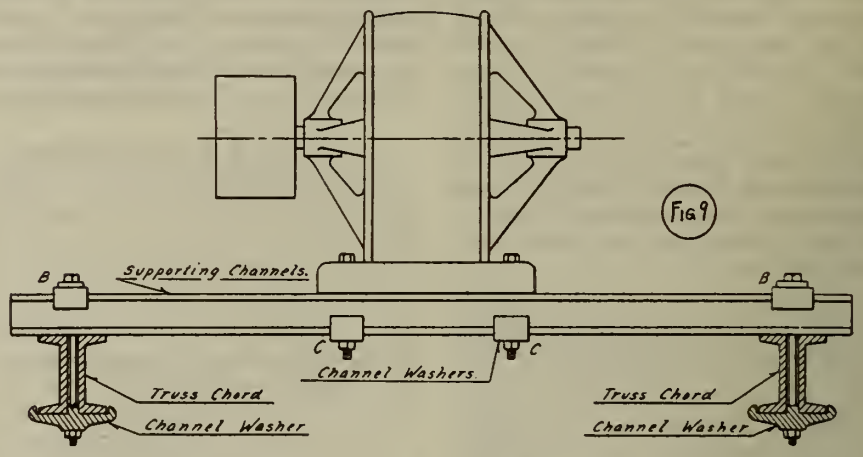

FIG. 9—SECTION A-A OF FIG. 6

tural steel frame of the building. A man standing on such a floor is, therefore, liable to receive a severe shock. It is for this reason that it is probably usually the best practice to place a wooden floor on a steel platform around the motor, particularly if it is high up in the roof trusses, because if a man fell from such a location it would probably be fatal. The amount of wood in such a floor should be maintained at a minimum.

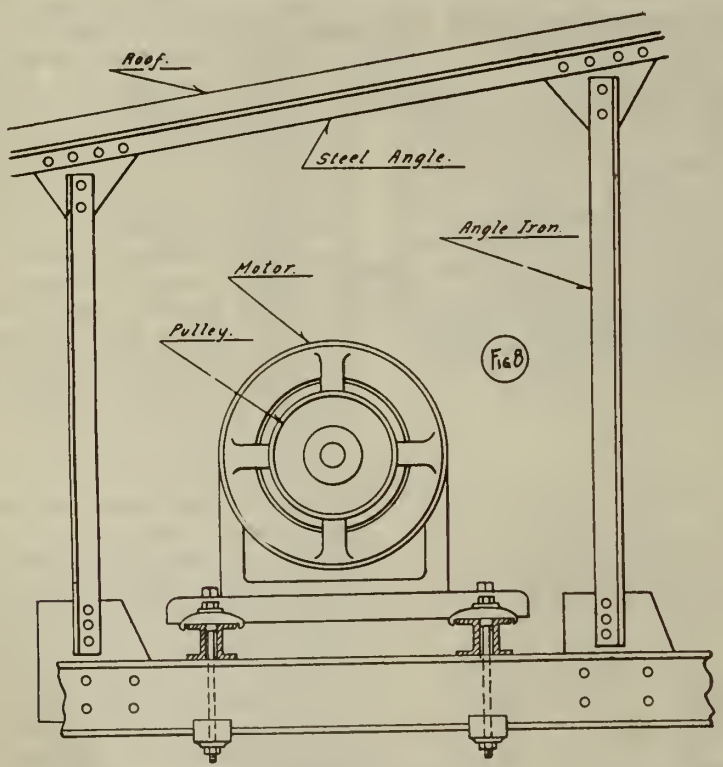

FIG. 8—MOTOR MOUNTED ON CHANNELS CLAMPED TO STRUCTURAL STEEL ROOF TRUSS.

column of the table, and also in combination with small I-beams.

No floor is shown in the motor platform in Figs. 8 and 9, because practice differs in regard to floors on structural steel motor supports. Some concerns insist rigidly upon the elimination of wood, in which case floors of standard checkered steel plate can be used. Such floors are, however, of necessity always grounded on the struc-

CONVERTING A PIPE THREADING MACHINE INTO A LATHE

By J. M.

The following description as to how we made a pipe-threading machine serve the purpose of a lathe may be old to some of your readers, but on the other hand it may be new to others. We had occasion to use some lengths of 2¼ in. round iron as shafting, the ends of which had to be turned down to 2 in. to fit the couplings, and to suit the supporting bearings the shafting had to be turned down to 2 ins. at various places.

Having no lathe capable of doing the work, resource was had to the pipe-threading machine, and with fairly satisfactory results, notwithstanding that the machine was old and somewhat the worse for wear. The gripping chuck served as a driver, and the guides in the die head supported the shafting just where support was required. Two tools (right and

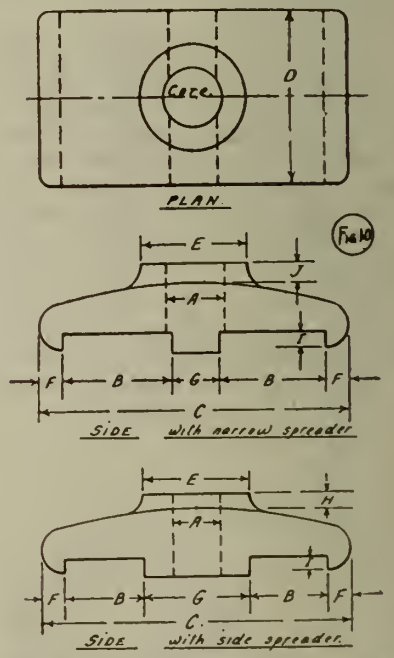

FIG. 10—CAST IRON CHANNEL WASHERS

left hand) were made to fit the tool slide rest, where the cutting-off tool usually fits, and by substituting a nut and screw arrangement for the rack and pinion gear we had a very serviceable lathe for the work in hand.

Mr. A. R. Dooley, Leitchville ,Sask., writes: "I am very much in favor of the change to a semi-monthly paper. I enjoy POWER HOUSE."

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Readers are invited to send in answers to these problems, as they have been chosen for their interest and application to the practical side of power plant operation.

Perhaps you, too, have some pet problems, or hard nuts which you would like to ask your fellow engineers; if so, send them along for the benefit of others.

Answers, together with the original question, will be published in the issues following the appearance of the question.

Questions Before The House

If a tube in your boiler developed a slight leak, as through a pitting that had gone through the tube, or a small sand hole, how would you stop the leak without dropping the pressure?

You have a compound engine, 11x19x 12 in. stroke, running at 260 revolutions per minute. Cut off in the high pressure cylinder is a ⅝ of the stroke. Cut off in low at 3-4 of the stroke. What is the horse power aproximately?

In the case of the above engine, what is the probable steam consumption per hour, and what size would you have to make a pump to supply the water consumed to the boiler?

10. Why is a horizontal engine, running over, provided with guides top and bottom? Which guide does the pressure act on, and why?

11. A cylinder 24 in. bore, carrying an initial pressure of 100 pounds per square inch. Allowing 5,000 pounds per sq. inch on the studs, how many would be required, and what pitch should they be set at?

12. The stays in a horizontal tubular boiler have an allowance of 6,000 pounds per sq. inch. If the segment is 24 in. high and the boiler 72 inches diameter, what is the number and diameter of stays required?

Questions Answered

2. The amount of lift possible in any pump is governed by the pressure of the atmosphere, and the degree of efficiency in the mechanical parts of the pump. Strictly speaking, such a thing as lift does not exist, or suction either. The pump plunger partially exhausts the air in the suction pipe, and the pressure of the atmosphere acting on the free surface forces the water into the vacant space. The pressure of the atmosphere is approximately 14.7 lbs. per square inch. This corresponds to a height of 33.8 feet, and if a pump were perfect, and could create a perfect vacuum in the suction, it would "lift" from this height. Practically, the average pump is limited to about 25 feet, due to leakage through glands, valves, pistons, etc., and friction in the pipe. The fitting of a foot valve is in no way a help when the lift has approached the limit, as in this case the valve represents an additional load for the pressure to lift.

In pumps which have a long suction pipe, but not necessarily a great lift, the fitting of a suction foot valve is a great help. By the help of this valve the pipe is kept full of water, and the first stroke of the pump creates an empty space and the atmospheric pressure is amply sufficient to overcome the resistance of the foot valve and pipe friction.—T.H.F.

9. Assuming initial pressure to be 90 lbs. per sq. inch. Cut-off takes place at ⅝ of stroke, giving a ratio of expansion of 1.6 in the high pressure.

90÷1.6=56.25=Mean pressure during stroke.

This is expanded at the end of the stroke into the L.P. cylinder which has an area in the proportion of 1.3 of the high pressure cylinder. The cut-off takes place at ¾ stroke, giving a mean pressure in the L.P. cylinder of 14 lbs. The M.E.P. of high pressure will be 56.25 less 18.75=37.5 lbs.

$$\text{The M.E.P. referred to low will be } \frac{\text{M.E.P. of High}}{R} + \text{M.E.P. of Low} =$$

$$\frac{37.5}{3} + 14 = 26.5$$

$$\text{H. P.} = \frac{19^2 \times .7854 \times 26.5 \times 11 \times 520}{33{,}000 \times 12} =$$

108.5 I.H.P.

An engine of this type would consume, say, 25 lbs. steam per H.P. per hour.

108.5×25 = 2,712.5 lbs. per hour.

$$\frac{2{,}712.5}{62.5 \times 60} = \text{cubic feet per min.} = .723 \text{ C.F.}$$

.723×1,728 = say, 550 cubic in. per min.

Allowing the pump to be 75% efficient, that will be

$$\frac{550 \times 4}{3} = \frac{2{,}200}{3} = 733 \text{ C.I.}$$

Allowing a piston speed of 50 feet per minute we have at, say, 50 strokes per minute a stroke of 12 inches which gives a diameter of, roughly, 8¾ inches.

11. A cylinder 24 inches diameter will have an area of 452.39 square inches. The total pressure on the studs will be

452.39×100 = 452.39 lbs.

Studs are allowed to carry 5,000 lbs. per square inch.

$$\frac{45{,}239}{5{,}000} = 9.04 \text{ square inches}$$

The circumference of the pitch circle will be

(24+2) × 3.1416 = 81.6816 inches.

Allow pitch of 3 inches, giving, say, 27.2. Make number of studs 28. Divide 9.04 by 28 = .323 sq. inch. for each stud. This corresponds to ⅝ in. dia. nearly.

28 studs — ⅝ in. diameter.

12. The area of the segment will be

$$\frac{4h^2}{3} \times \sqrt{\frac{d}{h} - .608} = \frac{4 \times 24 \times 24}{3} \times \sqrt{\frac{72}{24} - .608}$$

4×8×24×√(3—.608)=1,843 sq. inches.

At 100 lbs. per sq. inch total pressure = 184,300 lbs.

184,300 ÷ 6,000 = 30.7 sq. inches.

A pitch of 10 square inches would give 18.43 stays. Make stays 19 in number. 30.73 ÷ 19 = 1.6 sq. inches per stay. Say 19 stays of 1½ inches diameter.

PERSONAL

Frank J. Tone has been made president of The Carborundum Company of Niagara Falls, succeeding the late Frank W. Haskell. George R. Rayner has been made vice-president, succeeding R. B. Mellum of Pittsburgh. F. H. Manley retains the office of treasurer.

Stone Tool & Supply Company, Detroit, Michigan. Lieutenant Fisher, before entering the Service was connected with the Curtis Aircraft Corporation and the Continental Motors Corporation, Detroit and Muskegon.

Progress in New Equipment

PORTABLE CONVEYORS REDUCE COST OF HANDLING COAL AND ASHES

TO secure economical operation and greater efficiency in handling material, labor must be supplanted by machines, and those selected which are best adapted for the particular work. Men with wheelbarrows are too costly to use in storing, moving or loading material, but, at the same time, the old style conveyors required a great deal of labor in shovelling the material up into the receiving hoppers.

A new type of portable conveyor, which cuts the labor of feeding one-half, is shown in the accompanying illustrations. The most distinctive feature of this machine, called the scoop conveyor, is the scoop on the feeding end, which can be pushed or completely buried in

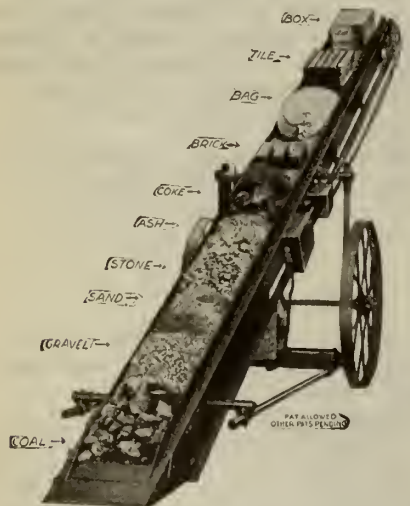

FIG. 1—A 19 FT 8 IN. CONVEYOR EQUIPPED WITH 16 IN. WIDE BELT AND DRIVER BY 2 H.P. MOTOR.

the material to be conveyed. This makes it possible to simply scrape the material onto the carrying belt, instead of lifting it up by shovelfuls into the feeding hoppers of ordinary conveyors.

Another exclusive feature of this machine is the construction of the sides or skirt plates, as they are called. These form a trough, which enables a 12-inch wide belt to equal in carrying capacity a 20-inch ordinary troughed belt. This is readily understood when one remembers that on a troughed belt the material is carried in the centre or trough, that on the sides falling into the trough or rolling back, whereas the side plates on the scoop conveyor hold the material together, giving the whole width of the belt carrying effectiveness. It is due to the skirt plates, also, that a 24-ft. long scoop conveyor will convey material as high as a 30-ft. troughed belt. The resultant saving in belt expense is considerable, as two new 12-inch x 24-ft. scoop conveyor belts can be purchased for the price of one 20-inch x 30-ft. troughed conveyor belt.

Actual Savings

The money savings resulting from the use of a scoop conveyor are due, first, to the saving in labor; second, to the speed at which material is conveyed. In comparison with handling material by hand, one or two men with a scoop conveyor will do the same work as from four to twelve men, depending upon conditions. The scoop conveyor will load trucks in one-fourth to one-sixth the time required by men shovelling. It often enables one truck to do the work of two trucks and of getting two days' work done in one day.

Storage capacity is another factor of saving attributed to this machine, as it increases the available capacity of a shed or yard space by enabling the men to pile higher.

FIG. 2—UNLOADING FROM WAGON TO STORAGE PILE.

A few statements of actual savings made by the use of portable conveyors may be of interest:

Gay Bros. Co., (Cavendish Woollen Mills), Cavendish, Vt. One man now used instead of four to pile coal for storage and to move it into boiler house. Average saving is $7 per day.

Baird Machine Co., Bridgeport, Conn. Reduced yard force from five men to one. Now unload coal from cars quickly, without having to pay demurrage charges.

FIG. 3 LOADING TRUCKS WITH A CONVEYOR.

Fonda Glove Lining Co., Fonda, N.Y. Load from 2 to 3 tons of soft coal from ground into auto trucks in from 3 to 5 minutes.

Colonial Steel Co., Pittsburgh, Pa. Unload coal from hopper cars with scoop conveyor at 50 per cent. of former cost. They figure machine has paid for itself more than once in a year.

J. L. Prescott Co., (shoe polish manufacturers), Passaic, N.J. Former cost of unloading coal from cars and putting it into storage bins was 28c per ton. It is now done with a scoop conveyor at 4c per ton, or a saving of 85 per cent.

Marcus S. Wright, (miner of foundry sands and clays), South River, N.J. Before using the scoop conveyor employed 6 men to load railroad cars. Now do the work with 3 men and get out larger tonnage. Load 150 to 175 tons of silica sand into cars with scoop conveyor in a 9 hour day with 3 men, which was impossible with 6 men working without the machine.

FIG. 4—UNLOADING FROM COAL CAR TO STORAGE PILE WITH A SCOOP CONVEYOR.

Capacity and Uses

The carrying capacity of the scoop conveyor, based on handling coal, is one ton per minute, provided a sufficient amount of coal is maintained at the receiving end of the machine. If the storage pile is of sufficient height, one man can easily feed one ton in one and a half minutes, or if the pile is low, he may require from two to four minutes. Where speed is required two men may be provided for feeding. In unloading hopper bottom cars the machine and one man can remove one ton per minute.

Large size coal, coke, crushed stone, etc., fed by one man, require from three to six minutes for one ton, or half that time with two men.

The scoop conveyor is used principally for storing, reclaiming and loading bulk material and light articles. There are an unlimited number of uses for the machine, in addition, such as elevating material to tanks or platforms in chemical and industrial works, feeding from cars and delivering into fixed conveyors or stoker magazines at power plants, etc. Almost any kind of material can be handled, such as coal of all kinds, ashes, sand, earth, crushed stone, blast furnace slag, ore, fertilizer, salt, chemicals, grain, bags and light packages.

The scoop conveyor may be used singly, in tandem or in triplicate, as may be required. The employment of sets of two or more allows for an increase in height of the storage pile or conveying distance. Fig. 5 illustrates three machines unloading coal from hopper cars up a long steep incline.

Construction

As may be seen from Fig. 1, the scoop conveyor is strongly constructed, light in weight, compact and portable. The steel frame holding the rollers and conveying belt is mounted on the wheels so the balance is perfect. One man, by inserting the pipe handles into the ends of the horizontal members, can easily lift and move the machine around.

FIG. 6—ONE MAN CAN MOVE THE SCOOP CONVEYOR FROM PLACE TO PLACE.

The electric motor or gasoline engine mounted under the frame transmits power to the conveyor by means of a chain and sprocket connection to a shaft extending beneath the conveyor. From a sprocket on the other end of this shaft the power in turn is transmitted to the driving sprocket, located at the upper end of the conveyor.

The carrying belt is a high grade of heavy duck and rubber conveying belt and duck cross strips. These transverse cleats are provided to prevent the material from slipping back down the incline.

The scoop conveyor is made in three different sizes: 13 ft. 8 in., 19 ft. 8 in., and 24 ft. The width of the conveying belt on any of these sizes may be either 12 in. or 16 in. wide, as desired. Size 13 ft. 8 in. elevates to a total height from the ground of 5 ft. 9 in.; the 19 ft. 8 in. size may be adjusted for any height from 6 feet to 9 feet, and the 24 ft. size may be adjusted for any height from 9 feet to 12 feet. The machines are furnished with either electric motor or gasoline engine, or where customer prefers to furnish and install motor himself, motor support and drive from motor shaft are provided.

For catalogue and other information address the manufacturers, The Portable Machinery Co., Inc., Passaic, N.J.

CUTTING STEEL UNDER WATER

An oxy-acetylene blowpipe of special construction has been used for some time past by a French firm for cutting steel under water, a feat hitherto considered practically impossible. The apparatus consists of a cutting blowpipe supplemented with a small diving bell to which compressed air is admitted to expel the water. The pressures of oxygen and acetylene required are much higher than those usually employed, and, naturally this pressure will depend upon the depth at which the apparatus is worked. At the trials now being carried out, ships' plates have been cut at a depth of 27 feet under water. It has been proved that arc cutting can be carried out in a similar way, but the apparatus is slightly more elaborate.

Condensers or District Steam Heating

AN interesting problem in power plant economics has arisen in England where the super station located at the coal mine will likely be the plant of the future. These stations will supply the surrounding towns and cities with electrical energy generated in the most efficient plants that present-day practice makes possible.

A counter-proposal has been worked out whereby every little community, village and town would have its own electric station from which it will distribute power, light, heat and hot water at a cost of one-quarter of the best a super-electric station can possibly reach. This economy is made possible through the well-known fact that 90% of the heat supplied to an engine goes to waste in the condenser water and the use of exhaust steam for district steam heating would enable the power company to sell 50% instead of 10% of the heat value of the fuel.

The consumer would benefit through the comfort, cleanliness and saving of labor which would result.

Post-War Economy

WHILE the engineer is not again likely to have war necessities put forward with considerable emphasis as a reason for conservation, the necessity for economical operation still exists and the lessons learned should not soon be forgotten. The coal pile has assumed an importance in the eyes of the plant-owner commensurate with its ever-rising value, and the engineer will, of necessity, be judged by the use made of its possibilities for the production of power.

The power plant is an excellent example of man's ability to apply abstract science to commercial ends, and it is in the application of the chemical phenomenon of combustion and of the laws of thermodynamics that economies are effected or waste occurs. Any given plant can never be more efficient than its design permits, but anything short of maximum efficiency is in many cases easily remedied.

The engineer now has available excellent recording and testing equipment, and by keeping close check on the performance of the boiler room and engine room can pay for the equipment necessary over and over again.

Do You Keep Records Like This?

MUCH waste is due to want of records. As District Engineer to the Controller of Coal Mines, A. E. Edwards, in a recent address given in England, said he was much struck by the absence of records in all classes of steam plants, and cited an example of those which he occasionally ran across. At one place he was shown very careful records of the cold water used for a number of years but the manager had not the remotest notion of why they required 70 tons of coal a week, how they burnt it, or what duty they got from it; indeed, they knew they burnt 70 tons a week by dividing their annual purchase by 52.

THE British Admiralty is advertising in some of the papers that it has a number of German submarines for sale cheap, the only stipulation being that they shall be broken up. There are quite a heap of folks who would with pleasure tackle the breaking-up job.

AN agitation is on in England, and it promises to gain strength, the object of which is that husbands shall pay wages to their wives. But in the case of the well-trained man, who simply comes home and tosses his pay envelope into his wife's apron, what is going to happen? Will some courageous individual arise and suggest that the husbands shall be allowed a certain amount as salary?

Dollars Wasted in Pipes and Fittings

By T. H. FENNER, Associate Editor Canadian Machinery

INDUSTRIAL plant managers have been brought to a sense of realization of power plant costs during the last two years. The result has been a tightening up of supervision, and a close analysis of fuel, water, maintenance, and wages costs, with an appreciable reduction in these items in many cases.

There is another item which it is more difficult to keep adequate trace of, but which is responsible for many hundreds and even thousands of dollars loss in a year, according to the size of the plant.

Hard to Keep Track Of

The modern factory contains many thousand feet of piping, wrought iron, copper, brass and galvanized, and this piping is being constantly renewed, repaired, or altered. From one to twenty steamfitters and helpers are kept busy on this work, varying with the extent of the buildings, and keeping track of all the material used becomes a matter of great difficulty, unless a very rigid system is in force. This applies to the power plant itself and to all the piping through the factory.

Generally speaking, it is in the smaller plant that the greatest waste of both time and material takes place, owing to want of a proper system, but even in many large plants, where the organization is on a much better basis, the loss, though smaller in proportion to the general expense amounts to large sums in the aggregate.

The Case of the Small Plant

Take the case of a small plant of from 100 to 200 horsepower, which are in the majority in this country. A plant of this kind may employ a steam fitter, or the man in charge of the engine and boiler room will attend to the repairs himself. In this case the element of time does not enter into the question so much as the man is usually employed on a standing wage basis.

There will be piping in a plant of this kind ranging from ⅛ inch diameter to six inch, and fittings for all these sizes. All fittings, pipe, packing and tools will be kept in the engine room, and the man in charge will have complete control of the ordering of material, and the using of it. He will be directly responsible to the manager, who cannot in the nature of things have much idea of the requirements of this department; and has to depend entirely on the engineer's judgment.

In a plant of this kind it is not usual to carry a large stock. As a rule, there will probably be from one to three lengths of each size of pipe up to 2½ in., the larger sizes not being carried, but ordered as required. Fittings for all these sizes will be on hand, and a collection of valves of various kinds. Now the number and variety of fittings would surprise a good many people who have not given the matter much thought.

There are elbows, forty-five degree elbows, tees, crosses, reducing bushings, couplings, unions, flange unions, locknuts, plugs, caps, side outlet elbows, etc. These are made in three different kinds; cast iron, malleable and galvanized, all suitable for different classes of work. Whether the right kind for the particular job is used or not depends on the knowledge of the man doing the job, and the durability of the job depends also on using the correct material.

The stock of these fittings carried on hand also depends on the good sense or otherwise of the man in charge. To be short of some particular fitting when it is badly needed, may result in the shut down of the whole plant, while on the other hand, to carry a large stock means tieing up money which could be better used elsewhere. In how many of these small plants could the engineer give a reasonable idea of the stock on hand at any particular moment, without a wild scramble through his stock? Very few, it will be found. What usually happens is that he takes a look in the bins when getting some fitting out, and orders a dozen of a few different kinds, to keep up the stock. This results usually in a surplus of the particular variety in most use, and a shortage of most of the others. Then the time comes when a particular fitting is needed, and needed badly. It is not there. The job can't wait, so what happens? Instead of using the cast iron fitting a galvanized fitting of the same size, and costing about 30% more, is taken. If that is not available then a larger one is used, and the difference made up by the use of reducing fittings at each end. This, again, brings up the cost of the material, and if there are several fittings on the job it may easily cost double. The time occupied in doing the job is increased, and even if the man's time does not count, the delay to a department of perhaps 25 to 50 hands is considerable. Then when the job is done, instead of examining the fittings that have been taken down, to see if their usefulness is entirely over, a hundred to one they are thrown into the scrap heap.

Can be Used Elsewhere.

Now, a fitting that may not be of much use on a high pressure steam line would be of use on an exhaust heating line, or a low pressure steam line. The same applies to the pipe. Although one part may be bad, the rest of it might well be used in some other part of the system. There being no check on the material used, or a very inadequate one, a number of fittings and several pieces of pipe are wasted on that one job alone. Now take the case of valves. Here is one of the most prolific sources of waste in most plants. To begin with, it is usual to find every make of valve known to industry represented on the system. This is bad in itself, for if a valve of one make is removed from a line, and another one substituted, there is nearly always a difference in length. This means that the length of pipe has to be pulled together or sprung apart, which entails a straining of fittings, which sooner or later results in another repair job. Again, a valve has a defective spindle. There is no spare spindle on hand, therefore, the whole valve has to be taken out of the line, and another one substituted. This usually entails the taking down of two or three lengths of pipe and fittings before a flange or union is reached. What becomes of the body of the valve, which is perfectly good? Mostly it is thrown in a corner and forgotten, and when another valve gives out on the body part the same procedure is gone through. Now if all valves when taken out of the line were carefully dismounted, and the bonnet, gland nut, and spindle put into separate bins or boxes, a good deal of money could be saved in the course of a year. In addition to this, one make of valve should be determined on as the most suitable, and whenever an old valve is replaced it should be by one of this standard pattern.

A Standardized System

In this way the whole of the system will be gradually standardized. Furthermore, a straightway gate valve should never be employed on a steam line, as it is almost impossible to keep them steam tight. Another source of waste is that of cutting a length of pipe, only to find it too long or too short by a ½ inch when put up. This means it has to be either cut and screwed all over again, or else the springing method so much in favor among steamfitters is resorted to. They get the pipe together, but it is in no condition to take up the normal working stresses, having been considerably strained already. The result is another repair job very shortly.

What About the Large Plant?

If this is all true in the small plant, what about the

large ones, where the extent of the piping system is multiplied many times?

Here the stock is usually carried in a special stock room, and the engineering department makes requisitions on the stock room for the material required. An adequate stock is usually kept on hand, and a card index system is employed which keeps a record of stock drawn and stock on hand. The stock room puts in its own requisitions on the purchasing department to replenish the stock. Even with this it occasionally happens that the stock room clerks allow some particular stock to get too low, and before their order has gone through a demand arises for the particular article that is out of stock. I have seen a whole section of a factory without heat for three days in the middle of winter, for lack of a seven-inch fitting. It is always well for the chief engineer or foreman steamfitter to keep tabs on the stock himself, and remind the stock clerk when anything is getting low.

So far as the stock room goes the the system is all right, and the chances of over or understocking not very great. However, when we come to the requisitioning of stock by the steamfitting department, the same elements of waste arise as in the smaller plant. We will take a case in point. The chief engineer receives a message that a bad blow of steam is occurring in a certain department. He sends a hurry-up call to the steamfitting shop, and a man is despatched to find the trouble. He sees the break, gets the steam shut off and starts in to make repairs. He sends his helper to the pipe shop for some fittings. The ones he wants are not there. There is no time to get an order signed by the chief, so the helper is sent to the stock room for such and such material, for which an order will be returned later. On the steamfitter's time slip will appear so much time, and so much material on this particular job. No record of material saved from the job, or whether the material charged was actually used, or some of it thrown back in the pipe shop, or how much scrapped. The only record is so much material issued from stock and charged up on the job.

Now, supposing some of the fittings have not been actually used on the job, some of the old fittings having been used again. These fittings are, as far as the books are concerned, gone, and their value written off. They may be returned to the pipe shop, or if the job is in an out of the way spot, left lying around. The result of this is that there is an amount of stock lying in the pipe shop which there is no trace of. Now, it is surprising, how much of this stock will find its way out of the gate. In a large factory men are dropping in to the pipe shop every now and again for a half-inch tee, or a two-inch elbow, and as the stock has not to be accounted for they get it. In the course of a year this amounts to a considerable sum.

If a new line is to be put up the same thing occurs. The man who is to do the job figures out what fittings he wants, gets a requisition signed, and receives the material. Anything over goes into the pipe shop, not back to the stock room, and the department is charged for the full amount. The same things occur with regard to valves, etc., as in the small plant, but on a larger scale.

The Remedy

The way to remedy this, in both large and small plants, is simply to check up closer on the material used, and this can be very easily arranged. Instead of simply having a time slip, with the material used entered in, a properly marked slip could be used, which would be a complete history of the job. First of all, it would be necessary to take stock of the material on hand, accounting for everything, good or bad. What is no good can be weighed, and put on the scrap heap. The next step is to have properly marked and classified bins, or stands, with two divisions for each class of fitting, one for old and one for material already used once. You are now in a position to keep track of your stock, which is, in other words, your money.

When a new line of pipe is to be put up, instead of issuing orders to put it up, get an estimate on the job from your staff, whether in a large or small plant, just as you would from an outside firm. Let them (or him) go over the job, see the best way to run it, and measure up the quantity of pipe and the number of fittings required. The accuracy of the estimate will, of course, depend on the man, but at least there is something to go on.

When the job is done, a return should be made shewing exactly how much material has gone into the job, and how much scrapped. This material should be checked off from your inventory, if the plant is too small for a stock room and a card index system, and a copy kept in the office, and one given to the man in charge.

If a repair job, the slip should show:—

Feet of pipe taken down.....
Number and size of fittings taken down .....
Feet of new pipe installed .....
New fittings installed .....
Pipe scrapped .....
Fittings scrapped .....
Pipe returned to shop for second use .....
Fittings returned to shop for second use .....

This is checked up against your inventory, and the fitgings scrapped added on to your scrap pile. This is surely not much trouble, and a monthly, two monthly, or six monthly checking up of your new, second-hand, and scrap material should pretty near account for every pound of material brought into the plant.

A system of this kind involves no extra bookkeeping and no extra clerical labor. It is just as easy for the department clerk to handle as the other one of merely charging up material used (or supposed to be used).

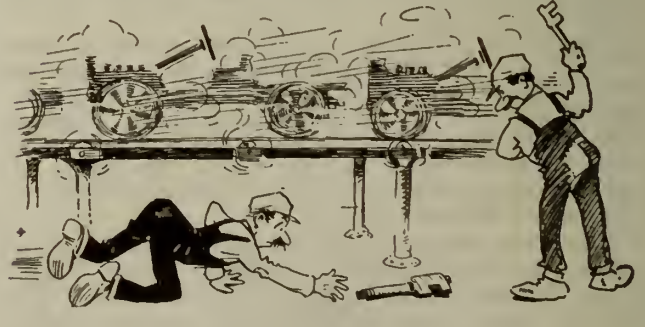
Whether the plant be large or small the amount saved in a year in this department would probably be a surprise to most managers, and in these days of high-priced material, every source of waste should be carefully guarded.

He Dropped the Monkey Wrench

HE sauntered into the office of the employment person. Lots of folks do the same thing. In fact the man in the employment office is some pumpkins these days. For the last three or four years folks haven't paid much attention to him, but things are a bit different just now.

However, this chap in question was looking for a job. He didn't have one—in fact that's the reason why he was lookin' for one.

Of course it's proper now to ask a few questions. For some time it's simply been a case of going in and having the employment person hug you and pass you on to the



boss. He, in turn, hugged you and advised you not to work too hard. But they're gettin' more particular now.

"Where've you been workin'?" was the first query.

"Ford's."

"How long?"

"Year."

"Quit or fired?"

"Canned."

"Why?"

"Dropped my wrench and seventeen machines went past before I could pick it up."

The Operators' Point of View

HANDY HOMEMADE LEVELING DEVICES

Figs. 1 to 5 show homemade levels, which will answer for all ordinary purposes, four of them are on the same principle. They have all been used in emergencies for many years. A few

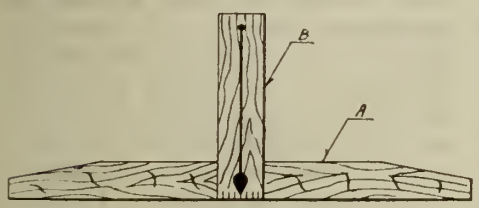


Fig. 1.

pieces of wood and a few nails, with a little work, will put any one of them together, ready to use.

To make Fig. 1, take a piece of wood, A, any desired length, nail on the upright piece B; drive in a nail and hang on the plumb-bob, as shown. When the line hangs exactly in the centre with the board on a test level space, turned either end, it is ready for use.

Fig. 2 is made from one piece of board. First nail on the plumb line and bob, place the board on some flat surface and draw a heavy line, A, close to the plumb-bob line; reverse the board and draw the heavy line B at the other side. With the plumb line exactly between these lines the level will be shown.

Fig. 3 is built on the same plan. A and B are the lines, the angle of the top is immaterial.

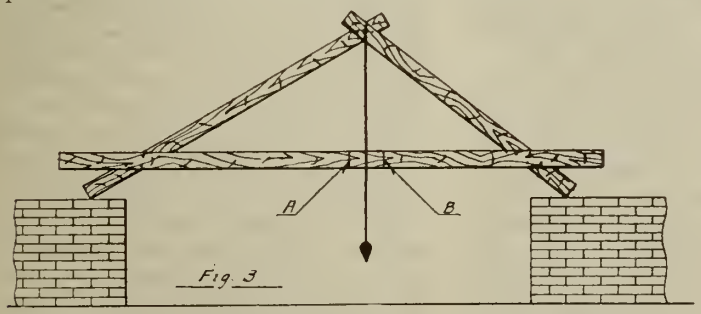

Fig. 3

Fig. 4 shows a leveling scheme often used by tile layers. It enables them to direct the grading of a trench with little climbing in and out of same. Of course, the length and height of the frame can be made to suit the desires of the maker.

Fig. 5 is on the same lines as the others. A hole is made on the bottom board instead of lines. A square of wood is nailed on the angle at A to strengthen it.

Portsmouth, Ont.

PAPER HANGING BY STATIC ELECTRICITY

For trick or demonstration purposes, to stick a piece of paper to the wall or ceiling without mucilage or any visible adhesive, take a piece of newspaper, say, 2x6 inches. Heat it over a lamp, stove or other source of heat, but do not scorch it. Place it under your arm above the elbow and pressing it between your sleeve and side withdraw it rapidly and quickly place it against the wall. If done in the best way the paper will have a sufficient charge of static electricity to hold it in place for from five to

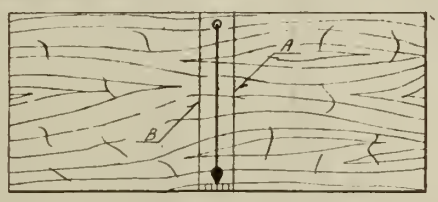

Fig. 2

thirty minutes. If it does not stick, do not attempt to make it do so by pressure; give it another passage between your sleeve and side, turning it end for end, for the second passage is an advantage. First attempts are sometimes unsuccessful, owing to not being quick enough, not pressing hard enough, or pressing so hard as to cause the paper to tear. After a very little practice one can cause the paper to adhere to the ceiling or the under side of a shelf or table for some time, or to a perpendicular surface for half an hour. Thick paper is not so suitable as newspaper, due to the greater weight for a given surface. Pieces of larger size can be worked by placing them between two sheets of paper and passing a heated flat iron over them, as though doing laundry work, then removing the said centre piece and placing it where de-

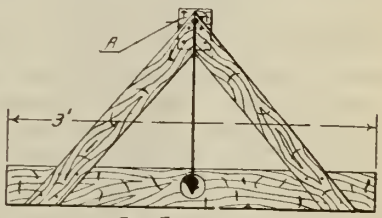

Fig. 5

sired. Of course, the surface to which it is applied must be a non-conductor of electricity, else it will not adhere.

REPLACING WORN ECCENTRIC—BRAINS vs. BRAWN

An eccentric on an old engine had become worn somewhat oval, as old eccentrics do, and in addition to this the threads in the holes for the set-screws had become very bad. I was advising the getting of a new eccentric, but lamenting how big a job it would be to strip the crankshaft enough to permit of slipping the old eccentric off and slipping the new one on, then replace everything else that had been taken off. One who heard me said: "I wouldn't undertake all that." When she was going to be shut down for a few days I would just knock the old eccentric in two with hammer and cold chisel and take it to M— (the foundryman) for a pattern, and let him make a new split one to fit. Split pulleys were an everyday thing with us, but the idea of a split eccentric had not occurred to me, yet the advantage in this case was just as great. Of course, his way was much ahead of mine. It saved so much really needless work.—By J. E. M.

An Engineer Runs Into All Sorts of Jobs

How a Structural Steel Tower Was Lowered Four Feet With Very Little Equipment or Staff to do it With—Essential Thing Had Been Overlooked in the Plans For the Work

By T. H. FENNER, Associate Editor Canadian Machinery

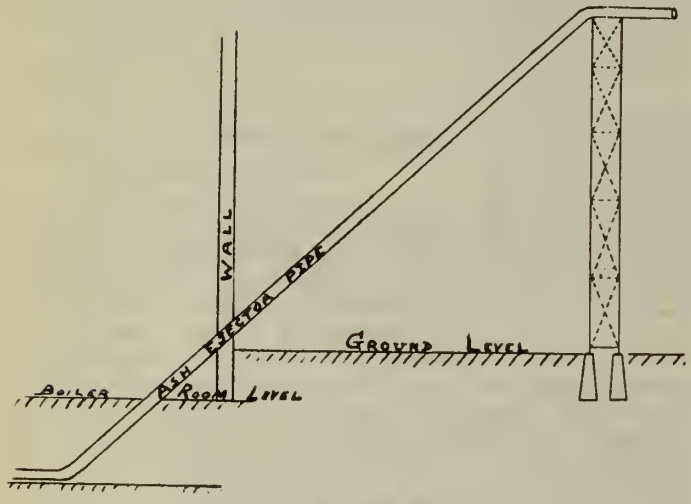
AS an instance of the unexpected propositions a mechanical superintendent is liable to run into, the following will be of interest.

A large industrial corporation was making an installation of coal and ash handing machinery for their power plant, and in connection with the ash ejector it was necessary to have erected a structural steel tower to carry the pipe from the boiler room by means of two channel irons resting on the tower and on the boiler room wall. The location of the tower and beams had been determined by the firm supplying the equipment from blue prints of the power house supplied them by the customer. The arrangement as originally submitted differed materially from that finally adopted, and in making the change one material factor was overlooked by all the parties concerned. The original and final arrangements are shown in the sketches accompanying. The tower was not to be supplied by the concern selling the ash handling equipment, they merely furnishing the design and location to suit their equipment. The factory engineering staff were looking after the erection of all the machinery. Feeling, however, that building structural was perhaps a little out of their line, the job of building and erecting the tower was given out to a constructional steel company. The approximate dimensions of the tower were thirty-five feet high, three feet in width at the bottom in one direction by ten feet wide in another, as shown in the sketch. The main posts were made of 3½ x 3½ x 5-16 angle iron, and the cross bracing of 1½ x 1½ x 3-16 angle iron. The corner posts were bolted at the bottom to four concrete piers, 5 ft. long, by 1 foot square at the top, by 18 inches square at the bottom

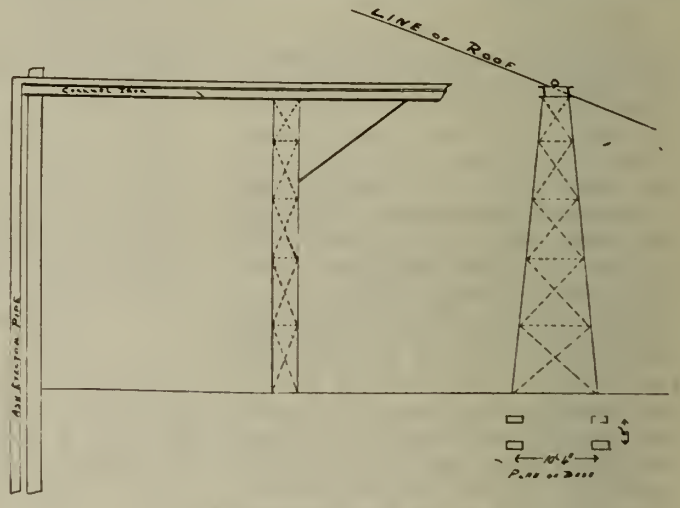
The foundations were placed by the factory staff in accordance with the drawings made by the firm supplying the equipment, and the steel construction people were notified that they could erect the tower and channel irons as soon as they were ready. In due course the gang arrived with the sections of the tower loaded on a large motor truck and men enough to make short work of the erecting. They started in right away to unload the truck and went at the job of coupling the sections of the legs together. The legs were made in two lengths of seventeen feet six inches, making when coupled together the required thirty-five feet. Two sides were laid on the ground with the base close to the foundation. Two or three angle irons were bolted across the posts to hold them together, and they were ready to raise up. Here an object lesson was obtained on the versatility of a well behaved motor truck. The two posts, comprising one side of the tower were raised by the combined efforts of the erecting crew till high enough to enable the truck to back in under them. They were then allowed to rest on the car and the car continued to back, thus raising the posts, when at an angle about forty-five degrees they were blocked up and the guy ropes fastened to the top end. A trestle was then put on the motor truck, catching the posts about half way up, and the car again backed up, this time raising the posts almost to the vertical. A good pull on the guy ropes and the two posts stood up in their place, and one side of the tower was erected. Everything was going fine, and in a very short time the other two posts were raised and the men started putting the bracing on.

The Trouble Started

The next operation was to put up the channel iron beams, and here was where the unexpected happened. It was discovered that one of the beams, instead of passing through the wall below the roof, would come out on top of the roof, while the other one would be under the roof, but too close up to it. How had this occurred? A hurried look over the drawing in the light of this new condition disclosed the fact that in altering the plans the angle of the roof had not been taken into account with the result already mentioned. The next question was, what was to be done? The steel men, anxious to get their job done and get away were for cutting the roof. As this roof had been re-slated only the year before at a cost of several thousand dollars, cutting holes in it was not desirable, especially a hole large enough to allow for the beams and the pipe on top of them. The contractors then washed their hands of the job and left, without any further comment. The chief engineer of the plant then decided he would lower the tower bodily just as it stood, lowering the foundations first and then bringing the tower down to them. It would have been easier to take down the tower first if he had the men available, but the staff at his disposal was woefully small and not particularly suited to a job of that kind, and the time necessary to dismantle and re-erect after would have entailed too much expense. The chief thing to guard against in performing the operation of lowering



ORIGINAL ARRANGEMENT

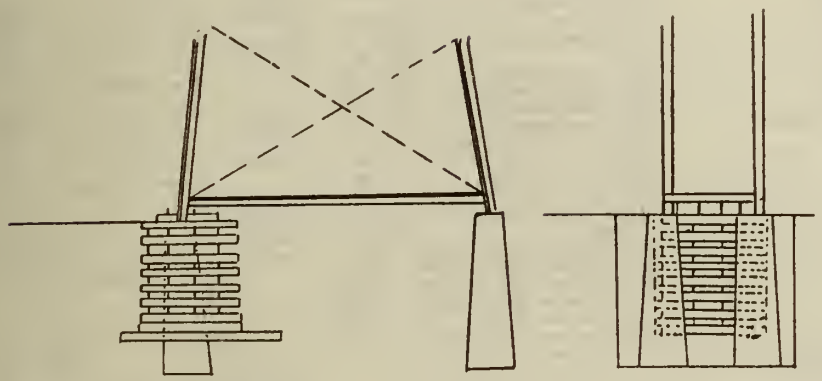


ARRANGEMENT AS ADOPTED

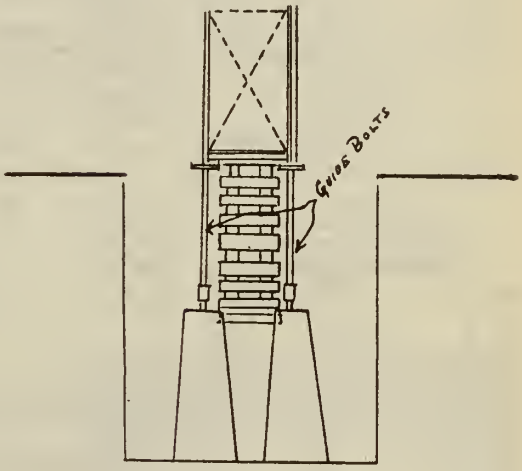
the tower lay in its capsizing on the narrow base, it being fairly stable on the 10 feet direction.

How it Was Done

The method adopted was as follows: Guy ropes were attached to the tower near the top, leading at right angles to the long base to counteract the tipping action on the short side. The ground was dug away from between the foundations to a depth sufficient to allow for the complete amount of lowering required. A crib work of 3 in. planks was then built in this space till it supported the tower on its lower cross-angle irons. The nuts on the holding down bolts of the two side piers were then taken off. The bolts projected through the base of the tower about 3 ins., they having been left long to allow for adjusting, after which they were to be cut off flush. A strong wooden horse, or trestle, which was in use around the mill for general millwright work was brought over to the job and placed close up to the posts of the tower parallel to its narrow axis. Two pair of triplex chain blocks were hung on the trestle and made fast to the base angle close to the post on each side. By heaving up on these blocks the base of the tower was raised to clear the foundation bolts on the two piers, the two on the opposite side being left fast to act as a counterweight. As soon as it was raised high enough to clear the bolts it was blocked up in this position and the chain blocks let go. One was made fast to the chain block and raised out of the pit, making room for a man to get down and dig. The ground was dug out where the pier had been to a depth of four feet and the companion pier was moved from its position and dropped in the hole. This saved lifting it out, and still left room enough for a man to work, making the excavation for the other pier. When this was done the earth was levelled off between the two piers, leaving the floor level at the new depth, and the first pier was dropped down into the place vacated by the second. Two long studs were made, six inches longer than the depth of the new excavation, and these were fitted with a screwed sleeve at one end, which sleeve also screwed onto the top of the holding-down bolt in the pier. The bolt was passed through the hole in the base of the tower and an efficient connection made between the tower and the pier, although they were four feet apart. This served to make one side secure, while the piers were dropped from the other side and the excavations made. (These precautions were necessary as the tower swayed considerably and there was at times a strong wind). When all the piers were in place and the long bolts in position, the tower resting on the blocking, all was ready for the lowering proper. A second trestle was brought up and placed on the other side and two more pair of blocks used. This made it possible to tip the tower on any of the four corners. The first move was to take the weight of one side of the tower on the blocks and remove one course of three inch blocking, then lowering till the tower rested on the next course. Having been level at first the tower was now three inches lower at this side than the other. The strain was kept on the long bolts on this side, and the chain blocks on the opposite side tightened up till the wooden blocking was free. This side was now lowered six inches, making it three inches lower than the side first lowered. This process was repeated alternately on each side till the full four feet had been attained and the tower rested on its foundations again four feet below its original level.



BLOCKING BEFORE MOVING PIERS.



READY FOR LOWERING

CURIOUS INJECTOR OPERATION

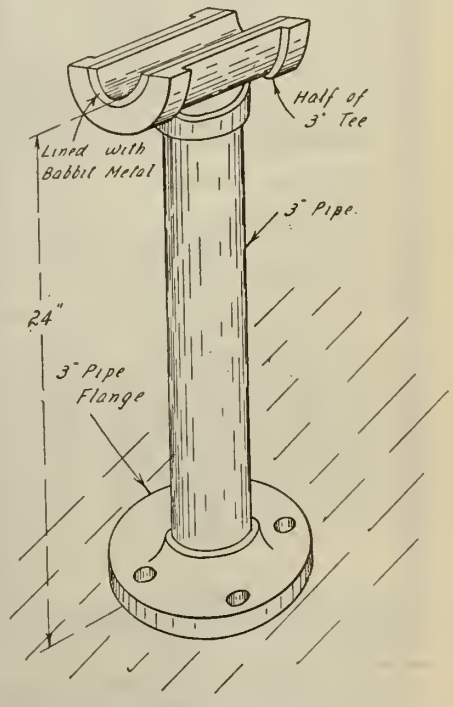
While with a prospecting company the increasing demands on our steam supply resulted in the ordering of a second boiler to the plant, and of a size equal to that of the one already there. The feed water was drawn by injector from a spring of water about 125 feet away, the total rise being perhaps eight feet. The water from the pumps in the pit was unfit for boiler use. By the time the second boiler was set up there had not yet been pipe enough arrive to run a line from the second injector to the spring and the line already there was only as large as the injector connections. Both injectors were of the same size. By way of getting the second boiler into operation without further delay, its injector was connected into the existing line by using a tee, the supposition being that by this means one boiler could be fed at a time. This device worked O.K. except that when only one injector was working (and it did not matter which one) there would be air enough leak in through the other injectors' overflow to cause the working injector to spit somewhat like a cat, perhaps twice a minute. When both injectors were working at the same time there was no spitting and apparently the two injectors, working together on the size pipe line normally supposed to serve only one, had no difficulty in each getting plenty of water through for its needs.—J.E.M.

SUBSTANTIAL ARMATURE STANDS

By Joseph D. DeWitt

(Copyright. All rights reserved.)

The best and most substantial support for small armatures that I have ever seen was made of pipe fittings. One



ARMATURE STAND.

of these stands is shown in the attached illustration. Two like this are required to support each armature. The upright is of 3 inch pipe and the base or foot is a 3 inch reducing flange. An old flange may be used. Screw holes are

SUBSTANTIAL ARMATURE STANDS

(Continued from page 175)

not necessary in this flange. The grooved top, which holds the armature shaft, consists of a 3 inch pipe tee, which has been cut in half on a shaper and babbitted so that the armature shaft will not be damaged. These stands are very rugged and are of little value except for holding armatures, so there is little trouble keeping them in the shop.

NEW AGENCY

E. J. Philips and Sons, Hamilton Trust Building, Queen Street, Toronto, have been appointed sole Ontario representatives for the Blonck Efficiency Meter and the Republic Flow Meter. Mr. Philips is well known to Canadian engineers and has a wide knowledge of the stationary engineering field. The Blonck meter is well recognized as one of the most efficient aids for the securing of efficiency in the boiler room. The Republic flow meter for measuring the flow of water, air, steam and gases, owing to its use of an electric registering and indicating circuit, is free from the errors usually encountered in flow measurement.

NEW PUBLICATION

"Over 1,000 Scoop Conveyors" is the title of a 20-page folder just published by the Portable Machinery Co., Passaic, N. J. This folder, replete with illustrations showing the various uses of the scoop conveyor, describes clearly the labor, time and money-saving features of the machine in storing, reclaiming, loading and unloading material, such as coal, coke, ashes, sand, gravel, crushed stone, fertilizer, cement, chemicals, etc. Thirty-two letters from users are printed testifying to the merits of the machine and eighty-four letterheads representing additional concerns who have written commendatory letters, are reproduced.

Copies of the folder will be sent gratis to those interested upon request to the manufacturers, the Portable Machinery Co., Passaic, N.J.

STEAM CONVEYOR vs. MANUAL LABOR—RELATIVE COSTS OF ASH HANDLING

Many engineers and power plant executives have been surprised when they quietly sat down and figured out for themselves the saving that resulted when their ash wheelers were replaced by a steam jet ash conveyor.

The American Steam Conveyor Corporation, Chicago, recently received a letter from the manager of the Big Mine of Canada, which is owned by the Canada West Coal Company, Ltd., Taber, Alberta, in which comparative figures were given showing the relative costs of handling ashes by the two methods.

The boiler plant of the Big Mine contains a battery of one 500 and five 150 horsepower boilers operating continuously. An American steam ash conveyor was installed, replacing the use of men and horses. The ash handling costs before and after the steam ash conveyor are as follows:

Cost of Ash Disposal Previous to Installation of American Steam Ash Conveyor Per 24-Hour Day

2 ash wheelers	$ 5.44	$10.88
1 teamster	4.08	4.08
1 horse and feed	1.50	1.50
		$16.46

Cost of Ash Disposal After Installation of Conveyor

1 laborer (9 hours)	4.08
Saving, 24-hour day	$12.38

(This laborer acts between fire cleanings as assistant fireman and boiler room helper.)

The ashes are left on the boiler room floor in front of the boiler until the cleaning is completed, and are then put into the conveyor, which handles the complete cleaning in about seven minutes. The boilers are cleaned every two hours.

It will be seen that the actual time the laborer spends at work handling ashes is relatively small. If the time spent on other work was charged against that operation the savings would be decidedly greater.

These figures bring home forcefully the economy that results from the installation of labor-saving equipment and emphasize the importance of carefully watching every item of boiler plant expense.

EFFICIENCY IN BELT DRIVES

By D. Street

In almost every factory and machine shop a certain amount of power is wasted in transmission through driving belts, the percentage of loss depending on the attention paid to the matter. Slipping, the trouble most frequently encountered, is common to all classes of belting, and generally speaking the remedy applied is to cut and tighten, or "take up" the belt so that it will run free from slackness with a better grip of the pulley; but probably more belts are broken and prematurely destroyed in this way than by actual use, not to speak of the additional load thrown on the engine and the consequent waste of power. To overcome slipping, many engineers incline to the principle of using belts wider than is actually necessary. This permits a heavier load to be carried, but when the practice is generally adopted all over a machine shop with fifty or more belt drives, the cost is very considerable. There is, however, a growing tendency to run belts slack, as not only is friction thus reduced and the life of the belt increased, but no power is wasted and the strain on the prime mover is considerably reduced. Immediately the tension is reduced the friction is proportionately lessened. Further increase of the arc of contact round the pulley (after the belt has been sufficiently slackened to have no initial tension) will not lessen the friction, but the load-carrying capacity of the belt is increased. As an example in many engineering shops it has been found that cuts 50 per cent. heavier can be taken on lathes where the arc of contact has been increased from 180 deg. (with a tight belt) to as high as 220 deg. (with a slack belt) and in one instance with a corn-crushing machine the increase in output was over 50 per cent. To permit of driving belts being run slack a proper belt dressing should be employed. Many belt dressings rely almost entirely on their capacity to "stick," due to the inclusion of rosin or tar in their composition, but others take the form of a non-sticky preservative

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS 242-248 244 SOUTH ST. NEW YORK. U.S.A.
FRICTION LOSS
An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

or belt food free from acid or alkali action, which is absorbed into the belt, rendering it pliable and highly effective, and at the same time protecting it from the effects of moisture, dryness, or chemical fumes. Such a preparation properly applied tends to give belts a velvety cling through the setting up of a vacuum suction between the belt and the pulley face, and will permit of slack running without fear of slip, even under the heaviest loads.

KNOCKING IN GAS ENGINES

By M. M.

A knock in a gas engine is frequently a warning of approaching breakdown. For this reason, it is generally inadvisable to allow an engine to continue running a moment longer than it absolutely necessary when a knock is heard. It would be interesting to know how many disastrous breakdowns, entailing personal injuries and stoppages of work, might have been prevented, had the engineer-in-charge not failed to heed the warning given by a knock in some part of the engine.

In probably the majority of cases, knocking is the result of lost motion in some part or other of the engine. For instance, the connecting rod brasses may have become worn, or the fly-wheel keys may have worked loose, and so on. As a general rule, the first thing the average engineer does when he discovers any knocking is to close up the big or the small ends of the connecting rods, or both ends if necessary, and in many cases this will cure the trouble.

It will occasionally happen with large engines, however, that, after fitting new connecting-rod brasses, a new and heavy knock will develop in the engine cylinder. This may usually be accounted for in the following way: The continual motion of the piston to and fro in the cylinder has worn away some of the metal of the liner, leaving a ridge at the part where the first piston ring moves up to each stroke. Since the new brasses are thicker than the old ones, the effect is to cause the piston to move a little further up into the cylinder each stroke, with the result that the first ring strikes against the ridge each stroke, causing a heavy knock. Of course, if the engineer in charge has taken the precaution to fit liners behind the brasses, as wear has taken place, so as to maintain the correct centres, the trouble in question is not liable to arise.

To prevent this new knock, it will be necessary to remove the ridge referred to by chipping and filing. If it be impracticable to do this early, the first ring may be removed from the piston until such time as the true remedy can be applied.

Sometimes the piston rings themselves will cause knocking or rattling through their being loose, and it is not always an easy matter to trace the knocking caused in this way. When, therefore, a knock cannot be at once located, it is advisable to test if the piston rings are a good fit in their grooves.

Looseness of the fly-wheel keys is a somewhat common cause of knocking in gas engines. The conditions of working in a gas engine are of course severe, much more so than is the case with a steam engine, and with the increased pressures and speeds now in vogue, it is no easy matter to get the keys to remain tight for long periods of running. The slightest amount of slackness is obviously serious, as in addition to giving rise to more or less severe knocking, it involves risk of damage to the keys, and fracture of the wheel boss, and possibly the crank shaft. Loose keys are always liable to be met with if the wheel boss has been bored slightly too large or at all out of true.

It is not sufficient that the fly-wheel keys be quite tight, but they must be a perfect fit. In numerous instances, the keys have been found as tight as possible, but the fly-wheel was, nevertheless, slightly loose, and a heavy knock occurred in consequence. An interesting example presented itself, when a large gas engine was reported to be knocking, and the owners, who were unable to locate the knock, arranged for a firm specializing in engineering repairs, to look into the matter. The firm's men commenced their investigations by first removing the connecting-rod and piston, with the object of closing the brasses, but this was found to have been done already by the owners. The piston-rings were next examined for slackness or breakage, but these were found to be in good condition and to fit perfectly. The fly-wheel key was then examined, but proved to be quite tight. As the cause of the knock could not be located, those concerned decided to give the engine a thorough overhaul, yet after the work of overhauling had been completed, the engine, on being started up again, knocked as badly as ever. The cause of the trouble was, however, discovered shortly afterwards by chance. The engine had been stopped again, and the man in charge of the job happened to place his foot on one of the arms of the fly-wheel by way of a rest, and in order to think the matter over. Whilst in this attitude the man felt a distinct knock on the sole of his boot. This gave the clue to the solution of the trouble; obviously there must be some slackness or lost motion in the fly-wheel. Although the key had previously been found quite tight, a close examination of the key and its keyway were now made, and the examination served to show, not only was the key badly proportioned and badly shaped, but the keyway had been badly cut, being narrower in the middle than at the ends. In short, only a short length of the key was really effective in securing the wheel to the shaft, and this was the cause of the whole trouble.

It has already been pointed out that the continual motion of the piston to and fro in the cylinder gradually wears away some of the metal of the cylinder liner, leaving a ridge at the end of the travel of the first piston ring. In extreme cases the wear is so pronounced, that the piston becomes quite slack in the liner, and this will sometimes prove to be the cause of the knock. Thus, when the explosive mixture is fired, the force of the explosion causes the piston to shake against the internal surface of the liner, and a knock is thus liable to be heard each explosion stroke. A knock of this character can scarcely be regarded as a serious one, since no undue stresses are likely to set up on any of the parts. What is perhaps of more importance than the knock is the loss which will probably occur by leakage of the explosive mixture past the piston. The remedy for the trouble is, of course, to re-bore the cylinder liner and fit a new piston, or else to fit both a new liner and a new piston.

One cause of knocking in gas engines, but one which is usually easy to discover, is undue clearance between the spindles of the different valves, and the levers which oprate the valves. When the valves are properly adjusted for lift, they are first opened very gradually by the cams which work the levers, and then more rapidly. When, however, there is a considerable amount of clearance between the valve spindles and the levers, the latter, instead of coming into contact at a moment when they are moving very slowly, only do so when the rate of motion has become comparatively great. The result is that the levers, instead of coming into gradual contact with the spindles, bang against them, thus tending to cause a knock. If now the valves lift easily, the force of the blow is relieved, and the knock will be of little importance, but if, on the other hand, much force is required to lift the valves, the knock is liable to become somewhat severe. In the case of the gas and air valves, comparatively little force is required to open the valves, because each valve opens at the commencement of the suction stroke, when the piston is really reducing the pressure against which the valves have to lift, and so assisting in opening them.

Now the case is quite different with the exhaust valve. This valve has to open at the end of the explosion stroke.

ENGINEERS

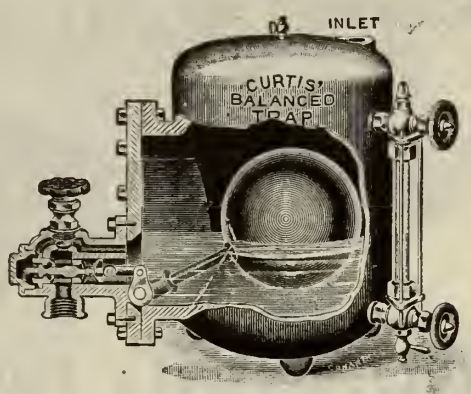
who *study* the Advertising Pages of

POWER HOUSE

naturally learn a lot about modern

POWER PLANT EQUIPMENT

which they really ought to know.



Five Superior Features of the Curtis

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on pressure varying from one to 250 lb.

when the pressure in the cylinder is considerable. Since, in addition to this pressure, the pressure of the spring which keeps the valve down on its seat during the admission, compression and explosion strokes have also to be overcome, not to speak of the weight of the valve itself, it is not difficult to understand that the force required to open the valve is considerable. Hence, when there is much clearance between the exhaust valve spindle and lever, the knock resulting may prove to be somewhat serious. The force of the blow is, of course, transmitted to the teeth of the skew wheels, which drive the cam shaft, and if these teeth are much worn, as they frequently are in engines which have seen much service, risk of breakage of the teeth is incurred. Knocking of a somewhat similar nature to the above will sometimes occur as the result of undue wear of the rollers, against which the cams work, the latter banging against the rollers once each cycle. Indeed, in old engines, where all the cams have become badly worn, the working of the engine has, in consequence, sounded like the rattling of a basket of pots.

Another somewhat common cause of knocking in gas engines, is early firing of the explosive mixture. Thus, if the charge is fired much before the piston reaches the end of the compression stroke, the general effect is to tend to check suddenly the motion of the piston, so that if there is the slightest lost motion in the moving parts, a more or less severe knock is liable to occur each cycle.

Too early firing may of course be caused through improper adjustment of the ignition arrangements, but it will sometimes occur when the adjustment is quite in order. The trouble will then generally be due to the deposit of carbon on the valves, the cylinder end, and on the piston.

When the trouble referred to is experienced, it is therefore well to look for evidences of carbon deposit, and should any be discovered, it should be removed at the earliest opportunity. Satisfactory removal can, as a rule, only be effected after the piston has been withdrawn. It is far from wise merely to loosen the deposit and trust to this being blown out through the exhaust valve. Unless the deposit is positively removed by hand after the piston has been withdrawn, there is every probability that the engine will soon suffer severely from scored piston rings and cylinder walls.

The Bureau of Mines, Department of the Interior, Washington, have issued papers Numbers 207 and 219. Paper 207 deals with combustion experiments with North Dakota lignite and gives an exhaustive summary of the results of numerous tests and trials which have been conducted with this fuel. Technical paper number 219 deals with subject of gas analysis and the necessity for it in the maintaining of proper combustion.

THE WORLD'S FASTEST SUBMARINE

The fastest submarine vessels in the world were designed and constructed for the British Navy during the war. They were evolved in response to the demand for submersible craft which could keep station with the fleet when cruising, and also undertake long voyages without the aid of mother craft. Many new features were embodied in this class, which has proved itself a conspicuous triumph of British engineering. Unlike other submarines they are fitted with steam turbines, which are used during operations at a high speed on the surface. Secondary propelling power is obtained from a heavy oil engine of 800 brake horse power, which drives a dynamo supplying electricity either to electric motors geared to the propeller shafts (for surface cruising at moderate speeds) or to electric batteries which store energy for propulsion under water. When submerged these vessels have a displacement of 2,1570 tons. They are nearly 340 feet long and have a double hull except at the ends. An exceptionally powerful wireless telegraph intallation is fitted for long-distance work. The aerials are carried on long, telescopic masts operated by a telemotor system. Electricity is also used for driving the air compressors and bilge pumps, while the steering gear and the hydroplane driving gears are controlled by a special hydro-electric system.

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH

Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

The Globe Valve Supreme

MUELLER Globe and Angle Valves are standard valves with all of the desirable features of high grade valves. The sectional view above will give you a fair idea of a few of the advantages it offers.

Look at the packing feature—a double seat enables you to re-pack the valve without removing it from the line.

The packing is a feature in itself; a specially formed, properly lubricated braided packing of flax reinforced with a lead core and copper wire strands; filled with graphite, absolutely sure in action; long-wearing and positively leak-proof.

Note the outside threaded bonnet with large hex, giving an added strength to the latest improved barrel type body and a positive wrench grip when necessary to remove.

We will gladly send you a sample valve for trial. Provincial Authorities have passed this valve—allowing a pressure of 175 lbs. We will be especially glad to receive requests from engineers for full particulars and samples of this valve.

Have you received a copy of our new 1919 Catalog "A"—just off the press?

Price, $1.00

MacLean Publishing Co.

Technical Book Dept.

143-153 University Ave., Toronto

Description
1. Packing ring forced against the leaky joint.
2. Inside split ring forced against the packing.
3. Clamp fits over rings. Set-screws hold all in a leak-proof unit

You Can Stop That Leak

—And stop it permanently—with a Yarway Pipe-Joint Clamp (formerly the Simplex).

It does not make much difference how big the opening may be—provided, of course, it is not beyond repair. Nor does it matter a great deal what is in the pipe—water, steam, gas, air, oil, ammonia, brine, etc.—the leak will be stopped absolutely.

And as long as the Yarway is left in place that joint will remain tight.

The principle of the Yarway Pipe-Joint Clamp is very simple. There are but three parts, as shown above—one packing and two iron rings.

Any workman can make the attachment without difficulty in a few minutes.

As an example of the way in which this serviceable clamp makes good, read what one user says:

The fact that from the date of its installation we have not realized that there is a steam joint at the point where placed, is sufficient evidence that it fills the bill.

Try a Yarway for 30 days subject to return if not satisfactory in every way Write to-day stating size of line.

For Severe Service

JEFFERSON UNIONS

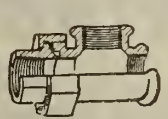
Pumps—frequently hard to reach—must chug away hour after hour, day after day, without stopping and without attention. Leaky unions have no place in pump service.

JEFFERSON UNIONS are particularly adapted to meet successfully severe service. The Brass Seat Ring makes the brass-to-iron joint which will not corrode and is easily disconnected no matter how hard or how long the union has been set up.

The Spherical Ground Joint makes possible an absolutely tight joint even though the line is not exactly straight on account of settlement or any other cause.

There are many other reasons why you should use "JEFFERSONS." They are not "just" unions and the name JEFFERSON stamped on the nut protects you from the doubtful variety. You'll find it mighty difficult to plug a leaky joint with a "just-as-good" promise.

Jefferson Swing Union. Allows widest variety of connections, ranging from a slight offset up to 90 degrees. For angle connections that cannot be made with simple elbow unions.



Jefferson Union Tee, with union or outlet. Has union end threaded either male or female. Should always be used where a union is desired near a tee.

All Male Union Saves two pipe joints between two female threaded parts.

Your Jobber will be glad to show you his stock of "JEFFERSONS." Your inspection will convince you of their merits. Write to-day for our Catalog "UNIONS" which shows the complete Jefferson Line.

TRADE MARK

Williams "Agrippa" Chain Pipe and Fittings Wrench

THEIR narrow, single jaw, with saw-tempered teeth for file sharpening when worn, gives these wrenches unequaled facility for holding and turning cramped and irregular fittings, flanges, short nipples, etc., etc., because:—

They grip upon surfaces where ordinary tools cannot—"Their grip does not slip."
They do work which tools with broader jaw will not.
They give more and better service than any screw-adjusted wrench made.
They "start" rusted fittings when all else fails—just the service to be logically expected of a fully warranted tool.

Remember, each Chain, like those in our well-known "Vulcan" Wrenches, is "proof-tested" in a standard tension machine to two-thirds of its catalog strength, and is certified. We guarantee absolutely every tool that leaves our factories. 7 sizes for ⅛ to 12" pipe and fittings.

Your dealer will serve you. Ask for Booklet.

GUARANTEED TO LAST THREE YEARS

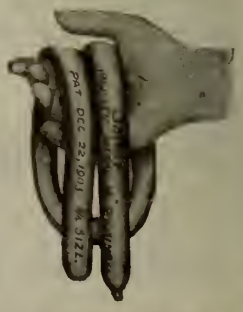
WITHOUT RENEWAL

Drop us a line and let us tell you all about this Remarkable Packing.

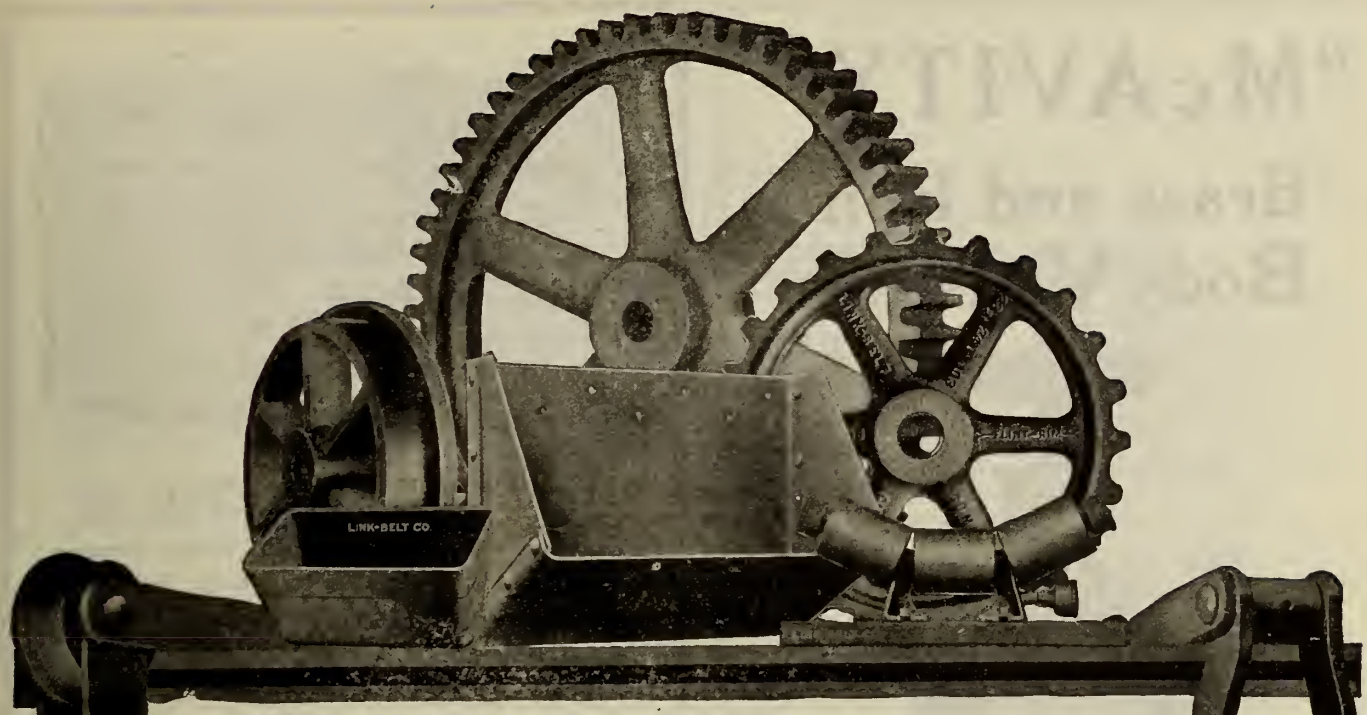
STEEL MILL PACKING CO., WINDSOR, ONT. Established 1899

AGENTS WANTED

Practically Frictionless



In Cotton Tubes



Need Repairs ?

DELAY in securing necessary repairs only means inefficient service and usually, in the long run, greatly increased repair expense.

We furnish repair parts for elevating and conveying equipment, including buckets of various kinds, belt conveyor parts, such as idlers and belting, Link-Belt and sprockets, gears and pinions, power transmission equipment, silent chain drives, roller chains, detachable Link-Belt, hangers, pulleys, pillow blocks, steel chutes and spouts, etc. Are all of high Link-Belt standard.

Our **FLINT RIM** Sprocket Wheels are made by a special process, providing a smooth, hard bearing surface for contact with the chain links. These sprockets last several times as long as ordinary sprockets and also greatly increase the life of the chain.

Write us about your requirements—no matter how large or how small.

WINNIPEG

I have always said to power plant owners years ago;- if we only had something we could would in place to take the place of fire bricks, blocks, etc., it would be what we needed. I did not then know about your material.

THE CHIEF REALIZED

that the weakest points of a boiler furnace lining are the joints between the bricks.

So he set out to find a way to remove this weakness, and he "discovered"

BETSON'S

REG. U.S. TRADE MARK PAT. OFF.

PLASTIC FIRE BRICK

Now he is not only a Betson user, but a Betson booster.

There is no mystery about Betson's. It is the pioneer and proven Plastic Fire Brick that has made practicable the one-piece furnace lining without joints. It has a record of 20 years' satisfactory service under all sorts of trying conditions.

You, too, can benefit by its use.

IT COMES IN A YELLOW TOP BARREL.

Investigate--Write for our literature. It will help you.

International Chemical Company

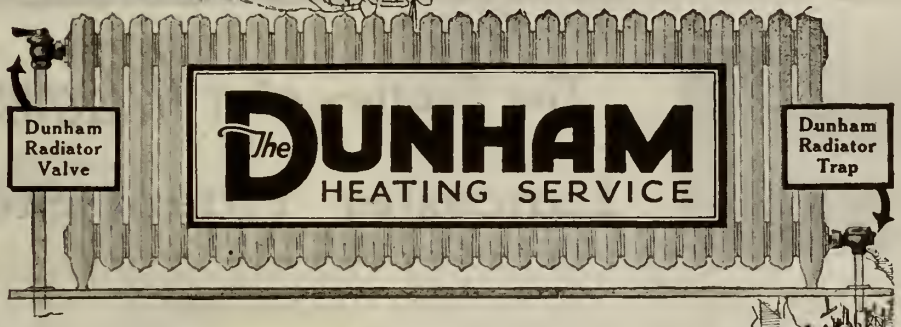
TORONTO, ONT.

A Solid One-piece, Jointless, Leakless Lining.

In All Kinds Of Buildings



From every ton of coal put under the boiler, Dunham Heating Service gives the maximum of heating comfort—not only in large buildings but also in small homes, thus proving that the fundamental principles of Dunham Heating Service are correct. It all goes back to the fact that the water and air that collects in the system must be quickly and automatically removed. This, Dunham Heating Service does by correct designing and the use of the exclusive Dunham specialties. Write for special data.

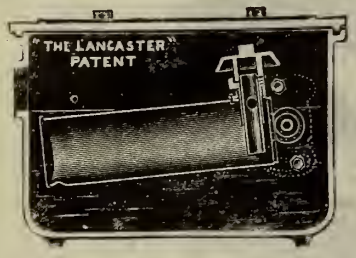
WILLIAMS & WILSON, LIMITED
Montreal, P.Q.

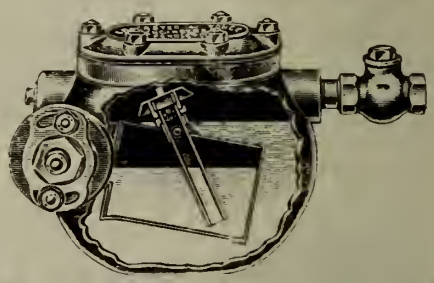


The Feature of Williams & Wilson's
Lancaster Patent Steam Trap

consists in the loose Disc Valve at the orifice of the discharge pipe in connection with a quick threaded screw motion, worked by the float. This valve is frictionless in action, and, being loose cannot stick to its seat. It is very prompt in its movements for opening and closing the discharge pipe, and the working parts are very simple and easily examined. It also acts as a Safety Valve, as any excessive pressure exerted against the face of the loose disc valve would, by virtue of the Quickness of the Screw Thread, force it open.

The Float being cylindrical and extending full length of the box gives greater capacity and at the same time permits the use of a smaller and more compact box. ⅜ in. trap is 8⅜ in. high, 10⅛ in. long, 6½ in. wide over all.

Write for full particulars.



"The Lancaster" Lifting and Marine Steam Traps

Similar in construction and action to "The Lancaster" Steam Traps, with the exception that being made with a much stronger box and fast lid, they will raise the discharging water 2 feet for each 1 lb. pressure of steam. The condensed water and air pass away with the greatest ease.

They cannot stick and have never failed under most Service Tests.

The Williams & Wilson, Limited, guarantee as well as that of the manufacturers stand back of every trap we sell.

We ship promptly. FULL particulars on request.

READ THIS

When called on to justify our demand for steel to manufacture our appliances, we had to show cause why, in the face of the abnormal demand created by war necessities, we should continue to receive our supplies.

WE SHOWED CAUSE, RECEIVED OUR SUPPLIES and CARRIED ON

We show you here an extract from our letter to the Fuel Controller, of Canada.

"We manufacture these appliances for the specific purposes of producing Fuel Economies in industrial steam plants and Private Steam Heating Systems.

Our records show that during the past year we have built and installed Condensation Return Traps and Automatic Boiler Feeders in Steam Plants to an aggregate of approximately 20,000 horsepower.

Our reports show that the average Fuel Economy effected in these plants, ranges from 10% to 25% of the fuel formerly used by the plants. This does not include small private heating plants.

Based on an average fuel consumption of four pounds of coal per horsepower hour, and a ten-hour daily run for three hundred working days, these plants would formerly use one hundred and twenty thousand tons per annum.

Under their new conditions with our appliances they are now consuming an average of 17% less fuel and doing more work.

THE APPROXIMATE AMOUNT OF FUEL SAVED IN THIS DISTRICT DUE TO THESE CONDITIONS WOULD BE ABOUT TWENTY THOUSAND, FOUR HUNDRED TONS."

We do not think we need to tell *you* any more.

The above savings are due to efficient handling of Steam Condensation and Boiler Feeding.

Do you want to share in these fuel economies?

If so, write us and get particulars of how it was done by means of our Return Traps.

This is the Return Trap

HOMESTEAD
Quarter-Turn Valves

The Valves for Hard Service

Expert workmanship and the quality of material used in the manufacture of Homestead Valves, together with their practical utility and long wearing qualities, have brought insistent demands from all fields.

The harder the service the more you need the Homestead Valve.

They are made for all pressures, in Straightway, Three-way and Four-way styles. They are made to suit all classes of material to be handled, and are, therefore, of brass, semi-steel and semi-steel with brass plugs.

Instal a Homestead Valve on your most troublesome line and note satisfactory results.

Why you get

better service
from
LUNKENHEIMER
"VICTOR"
GATE VALVES

THE disc is a solid wedge, seating on rings which are threaded into the body in exact alignment with the disc faces; the disc is guided by ribs cast in the body, and travels to practically a closed position before coming in contact with the seatring faces. "Dragging" of the disc across the seatring faces is thereby eliminated, preventing the wear so prevalent in valves employing loose parts.

When wide open the top of the disc seats directly beneath the stuffing box, relieves the packing from pressure and permits repacking while pressure is on.

The gasket between the body and bonnet flanges is an exclusive Lunkenheimer feature. It consists of a seamless copper wire partly embedded in a groove in the body flange; will not blow out and is practically indestructible.

Bearings are bronze bushed and all parts, including the seatrings, are renewable.

Inside Screw Stationary Stem and Outside Screw and Yoke Rising Stem types for working steam pressures up to 350 pounds.

Installing Lunkenheimer "Victor" Gate Valves means permanence and satisfactory service.

WRITE FOR DESCRIPTIVE LITERATURE

NEW YORK
CHICAGO
BOSTON
LONDON

WILSON FEARED THE BRITISH

THE American President crossed the Atlantic in the first place with the idea in his mind that his ideals would be thoroughly in accord with those of the French statesmen; but he was rather afraid of a conflict with the British delegates. He found in reality that his plan for peace terms was as far removed from the French plan as the two poles. Then he crossed to London and was surprised to find that the ideas of the two Anglo-Saxon powers were identical.

This situation, according to J. W. Dafoe in the May issue of MACLEAN'S MAGAZINE, explains much that has developed at Versailles. Further, it contains the promise of a close *rapprochement* between the two great English-speaking democracies for all time to come.

Mr. Dafoe has contributed a remarkably interesting article to this number of MACLEAN'S, lifting the curtain on many of the puzzling situations that have arisen overeas. As editor of the Manitoba *Free Press,* he is the dean of Canadian newspapermen; as the representative of the department of Public Information on the Canadian Mission to the Peace Conference, he was in a special position to learn what was transpiring. He tells of the really big part that Canada has played in the Proceedings and points out that Canada's status as a nation was firmly established in the eyes of the world when she was allowed separate representation.

A Dozen Other Features---Nationally Important

This May issue is full of articles of unusual significance for Canadian readers.

"SOLVING THE PROBLEM OF THE ARCTIC"
—By Vilhjalmur Stefansson

The second instalment of his remarkable story of the four years of exploration that he undertook for the Canadian Government in the region of the "Pole of Inaccessibility"—a harder place to reach than the North Pole.

"ORGANIZING FOR PEACE"
—By George Pearson

An article of the Great War Veterans' Association by a well-known author-soldier.

"THE CANADIANS IN SIBERIA"
—By Capt. W. E. Dunham.

A graphic story of what our forces did in combatting the Bolsheviki, by an officer who has just returned.

"SAFE IN THE SADDLE"
—By J. K. Munro

A review of affairs at Ottawa in which the opinion is expressed that Union Government for the time being is safely entrenched.

The National Idea

The articles in this issue of MACLEAN'S reflect the national idea—Canada's part in the Peace Conference, the political situation at Ottawa, the exclusive report of Stefansson's national explorations, the national organization of our returned men, the work of our forces in Siberia. The reader of MACLEAN'S gets a broad idea of what Canada as a whole is doing. The value of this issue—and of all issues—is very great, therefore, from an educational standpoint.
MACLEAN'S is the one magazine that should be selected for young Canadians to read.

Four capital stories by famous authors—W. A. Fraser, Lloyd Osborne, Frederic S. Isham and C. W. Stephens.

The Review of Reviews

An unusually fine array of articles is given in this department, selected from the best in magazines and periodicals the world over. Some of the titles are:

Planned to Destroy British Fleet.
How Mackensen Was Caught.
Events of War Foretold by Stars.
What is Life Like Beyond the Grave?
A High-born Bolshevik.
The New Life in Dry America.
Germans Were Ready to Capitulate.
Japan's New Foreign Policy.
The Many Kings of Jerusalem.
Is British Foreign Office Against League?
Ambassador Tells Story of Peace Ship.
Hindenburg—After the Armistice.

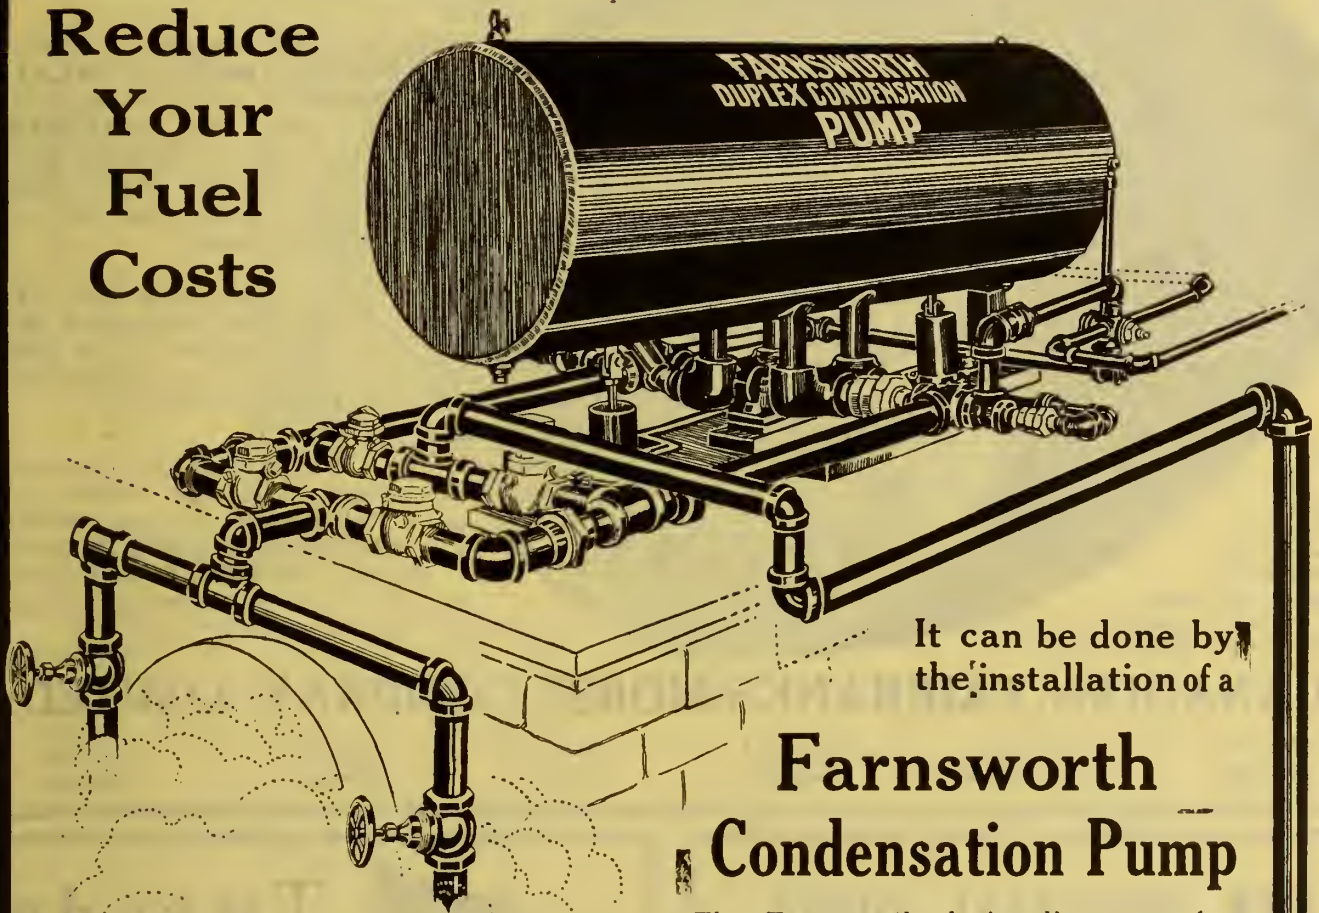
FAIRBANKS-MORSE
EVERYTHING MECHANICAL

Reduce Your Fuel Costs



It can be done by the installation of a

Farnsworth Condensation Pump

The Farnsworth drains lines carrying high vacuum between the engine and the condenser and will discharge the condensate to atmosphere or by the use of a small high pressure steam connection will pump the condensate to any point of use.

Large capacity provides a special service for taking care of any slugs of water that might accumulate in the exhaust line.

When the machine is in a filling position or receiving the condensation, the tank is equalized with the exhaust line and applies either high pressure steam to pump the condensate out of the tank or opens a vent valve to allow the condensation to flow to atmosphere by gravity.

This same machine will handle condensation from the exhaust line if the line should instantly change from a high vacuum to a low pressure and will pump the condensation to any point of use or to atmosphere.

HOT WELL ELIMINATED.

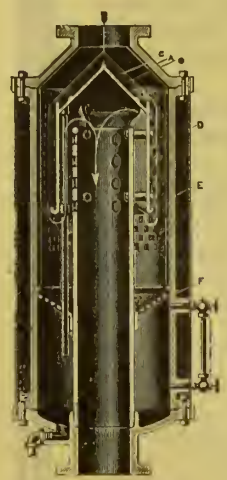
III IMPORTANT THINGS
TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

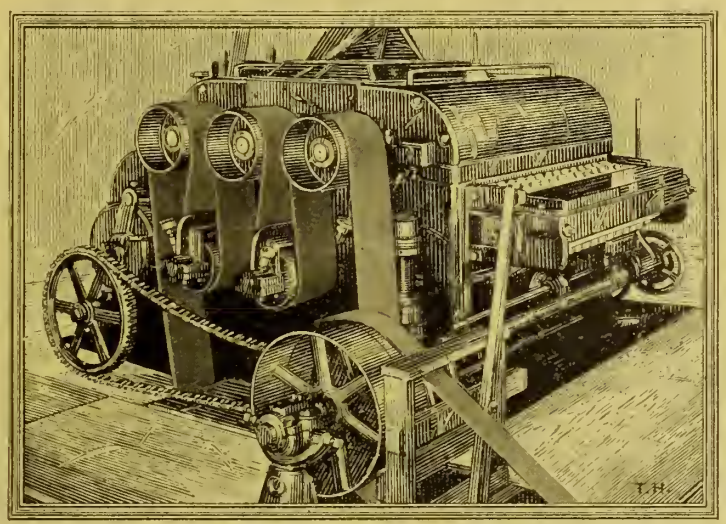
This illustration shows a Graton & Knight veteran in a Spartan Double Belt, 46 feet long and 8 inches wide. It is running every day in the plant of the Leroi Furniture Company, St. Louis, Mo. It has seen 4½ years of service. This belt-eating sanding machine wore out three 9-inch ordinary belts in eighteen months. Its cost has been 40 cents a week with long service to come.



For all drives designed in our Engineering Department the belts are proportioned so that the stress, due to the horse-power being transmitted, is never more than one-tenth of their ultimate strength. The rules employed are the result of extensive experience, and applied to your problems may show that you are using a belt too good or one not good enough for the work to be done.

The Right Belt in the Right Place

Here is punishment for *any* belt. And as usual SPARTAN is the belt that is game for it. It shows the right belting material in the right place. SPARTAN, greatest of pulley-grippers, flexible and elastic, is solving the problem of the trouble-making drive in thousands of plants. There is one answer and one reason—leather properly tanned and fabricated for a given purpose—a Standardized Series.

You can't think of any belting material that stands hard knocks the way leather does—or one that can be satisfactorily spliced or repaired. Leather has the tightest of frictional grip. It gives and takes as the need arises. It doesn't fray under the side slapping of shifters. After a long and useful life on main drives you can cut it into smaller belts and keep it earning money.

Graton & Knight Standardized Series Belts are made for the work to be done—from the first step in tanning. Very nearly 300,000 steer hides pass through our hands yearly. Think of the broad selection that gives us, the uniformity of quality possible. And installing any G. & K. Standardized Series Belt means the right belt in the right place—not merely a belt, but a belt for a *given* purpose.

Many of the best belted plants ask us to specify the belting for every drive. Try the plan yourself. Then, when buying, call for "Graton & Knight Brand—or equal." This won't commit you to buying our belts. It will put your buying on the one basic consideration—the work to be done.

Write for information about Standardization as applied to Belting

Never will this Tube Buckle, Bend or Split

Because of the divided floating head which compensates for the unequalled expansion of the tubes, due to the temperature difference between the water as it enters and leaves the heater, the

ALBERGER HEATER

is proof against troubles such as leaks, split tubes, cracked heads, etc.

On Alberger Heaters there is far less tendency to scale because tube corrugations cause the water to take on a whirling, scouring action.

You will avoid all expense and trouble common to ordinary heaters by giving your plant an Alberger Multi-Head Heater. Both Horizontal and Vertical Types of adequate capacities for every service.

50 % More Heat

Using no more steam, Alberger Heaters are guaranteed to transmit 50% more heat than straight tube heaters of similar size. They furnish hot water as fast as it can be drawn. No storage tank required.

THE FINANCIAL POST
OF APRIL 26TH CONTAINS:

DOMINION STEEL'S SHIP PLATE DEAL

Arrangement Promises to Work Out Well for Company and Shareholders

The continuance of work on the Dominion Steel Corporation's rolling mill at Sydney, N.S., brings to mind that this company has a very favorable agreement with the Dominion Government, and one which should be a good thing for the shareholders.

The company agrees to make plates (basic open hearth) to such thickness or size as required for shipbuilding, the Government to purchase 250,000 gross tons, and have the option of increasing the amount to 375,000 tons. Deliveries are to be made at the rate of 50,000 tons per year, the Government retaining the option of increasing this to 75,000 tons per annum.

The price for such plates is $4.15 per 100 lbs., or $83 per ton, and provision is made that this price may be increased to $4.25 or $85 per ton.

You will find further interesting matter on this subject in THE POST of April 26th.

THE PRICE FOR STEEL SOON TO BE ADJUSTED

Between the United States Railroad and Industrial Boards

NEW YORK.—From a technical market standpoint, according to Hayden, Stone & Co., the most encouraging event of the week was a new high price on this movement for Steel common. The figure reached is the highest since last November. Undoubtedly this anticipates an agreement between the railroads and industrial boards on the price level for steel. This is one of the acts to which the market has been steadily looking forward. It will be important, not only in the material improvement which it should shortly bring about, but even more for its psychological effect. No doubt it will be shortly followed by an agreement on the price for coal.

You will find further interesting matter on this subject in THE POST of April 26th.

Why not Buy the Best, when in market for Packing?

HOLMES' Metallic Packing

Is Guaranteed 3 Years

Lasts many times longer. 30 days' trial. Less oil. No cutting. Easily applied to any Steam Engine, Air Compressor or Gas Engine. Satisfaction or no pay. Write us

HOLMES METALLIC PACKING CO., Wilkes-Barre, Pa.

Incorporated 1897

McDANIEL IMPROVED STEAM TRAP

FOR HIGH OR LOW PRESSURE.

Steam can't blow through. They have large discharge valves and cannot be flooded from sudden flushes of water.

MAY WE SEND ONE FOR TRIAL?

Reducing Valves, Pump Governors, Relief Valves, Exhaust Pipe Heads, Ejectors and Steam Separators.

SEND FOR CATALOGUE.

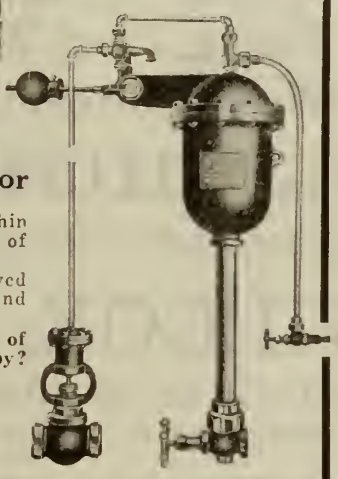
DARLING BROTHERS, LIMITED
Engineers, Manufacturers and Founders
120 Prince Street, MONTREAL, P. Q.

Pumps for any Service—Steam Appliances—Freight Elevators—Webster Vacuum Heating System.

Consult "Power House" Buyers' Guide
If what you want isn't advertised in this issue, consult our Buyers' Directory. If it isn't in our Directory, write us and we will gladly give you the information.

VIGILANT

Automatic Feed Water Regulator



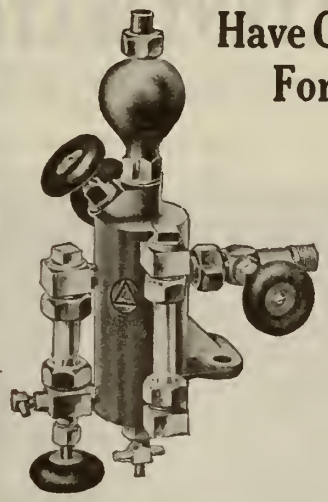
The "Vigilant" keeps water within ¼" of middle gauge regardless of load or firing.

Years of service test has proved it the utmost in reliability and efficiency.

Catalogue presents many points of interest. May we send you a copy?

The CHAPLIN-FULTON MFG., CO.
28 Penn Ave., Pittsburgh, Pa.

Detroit Lubricators
Have Given Satisfaction For Forty Years.



Built in a sufficient variety of styles to lubricate properly every type of steam engine, pump, gas engine, air compressor, etc.

Send to-day for catalog L 1. The information on lubricating devices contained in it will be valuable to you.

THEIR efficiency holds over half the world's trade.

Makers of Stewart Carburetors.

CANADIAN DETROIT LUBRICATOR COMPANY, LTD.
WALKERVILLE, ONT.

When the Board of Directors Visits the Boiler Room

One or two or more of them are almost sure to notice and to comment on the presence or absence of Diamond Soot Blowers.

Why?

First: Because it is not uncommon now-a-days to find men with considerable engineering training, as well as business men with much practical experience in power plant matters, on directorates. These men know the value of maintaining clean surfaces for the transmission of heat in the boiler.

Second: Diamond Soot Blowers are widely advertised and the results of many tests have been published in the editorial pages of dozens of technical and trade papers, so that even directors not closely informed on all phases of power plant operation, are familiar in considerable detail with mechanical soot blowers.

Third: Diamond Soot Blowers are installed on over 2,000,000 HP of boilers annually. Other plants with which the directors are associated or are familiar, are increasing their net profits to an appreciable extent by the use of Diamond equipment.

TO MANAGERS AND SUPERINTENDENTS:—

If your boilers are not equipped with Diamond Soot Blowers, what reasonable explanation can you make to your Board of Directors for your failure to utilize a proven method of reducing your fuel consumption 4 to 8 per cent., greatly reducing your labor costs and labor turn-over in the boiler room, and materially reducing your boiler repairs, at an expenditure which will enable you to earn from 100 to 200 per cent. on your investment annually?

For full information ask for Bulletin 162.

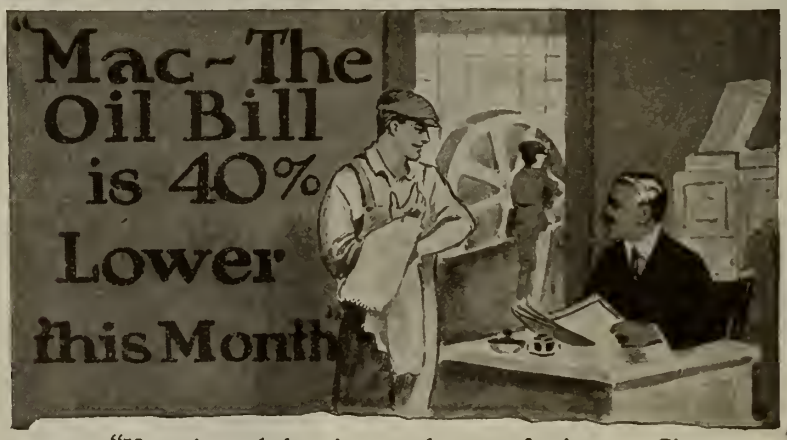
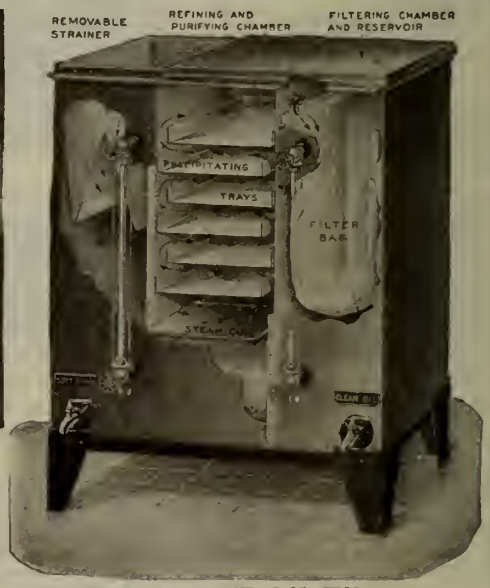
TORONTO OFFICE, TRADERS BANK BUILDING



"Yes, sir, and there's a good reason for it too. Since we installed the BOWSER Oil Filtering Outfit the men in the engine room have been competing to see who could save the most oil. They've cleaned the journal boxes, put pans under them to catch the drips and then put the salvage through the BOWSER Oil Filtering Outfit. We are now using the oil over and over again that was formerly wasted."

The BOWSER Oil Filtering Outfit is simple, compact, economical and reliable.



Bowser 7F Oil Filter

First, means a cleaner engine room.

Second, it cuts your lubricating oil bill considerably.

Third, IT PAYS FOR ITSELF over and over.

WRITE FOR LITERATURE DESCRIBING OIL FILTERING SYSTEMS SUITABLE FOR YOUR POWER PLANT.

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

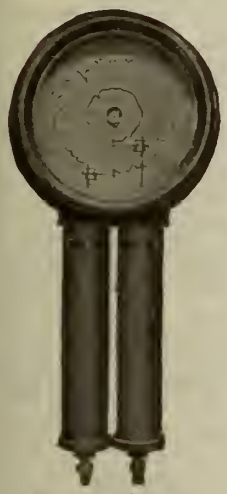
CO_2 AND TEMPERATURE RECORDER



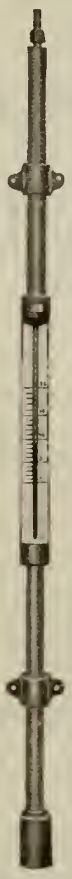
Record of CO_2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The Uehling CO_2 Recorder makes a complete 24 hr. record of your combustion efficiency and the CO_2 indicator at the Boiler Front holds the fireman responsible.

Get more Steam per pound of Coal and reduce your annual fuel consumption.

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.



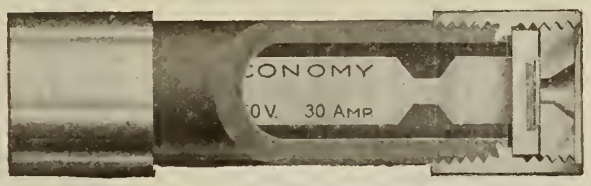
CO_2 Indicator for Boiler Front

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

Uehling Instrument Company

2008 Empire Building New York City



ECONOMY Renewable FUSES

are commended to the practical electrician and engineer because in performance they do all that could be asked of any fuses and, in addition, cut annual fuse maintenance costs 80%. This pioneer renewable fuse, when blown, is instantly restored to its original efficiency by an inexpensive "Drop Out" Renewal Link—the most efficient and economical of all renewal elements. It's the work of a moment for even a novice to replace the link and renew the fuse. ECONOMY renewable FUSES are used by representative houses in all branches of industry throughout North America, and are sold by most leading jobbers and dealers.

This book should be in the hands of every pump user. A postal will bring your copy promptly

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction*. Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs*. Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

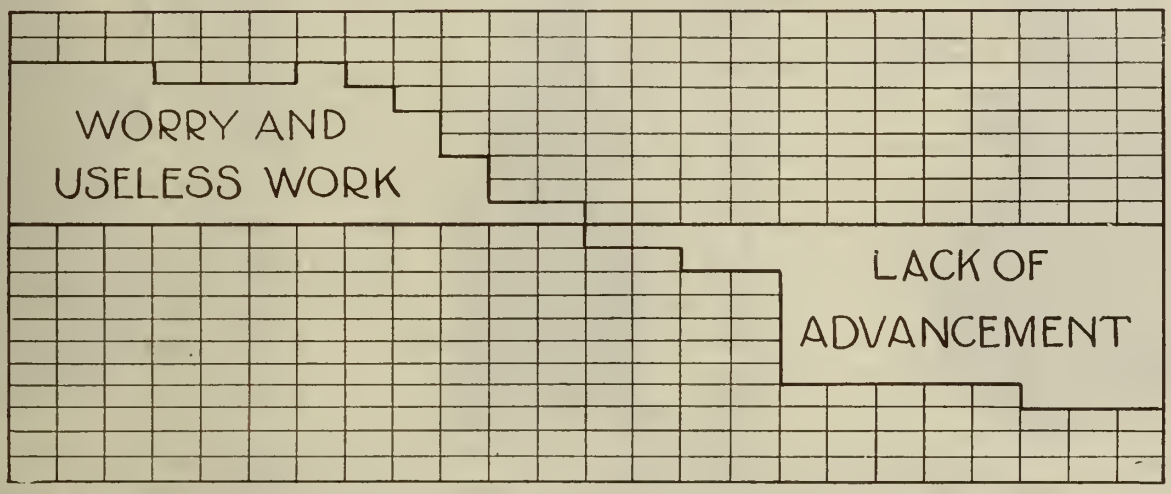
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

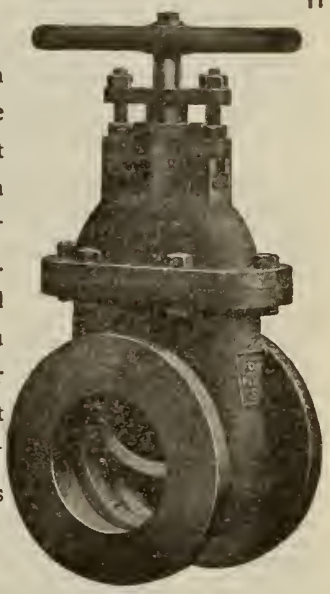
KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.



When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**

Boiler Room Efficiency Instruments

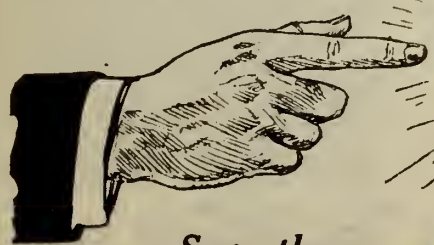
NO MORE GUESSING IN YOUR BOILER ROOM
THE DEFENDER SYSTEM (READS)

Draft, Temperature and CO_2 on each Boiler. Determine the Draft over the fire and at the last pass of the Boiler and the drop in Draft through the Boiler—that gives the highest percentage of CO_2 in the Flue Gas and the lowest Flue Gas Temperature.

This gives the highest Boiler and Furnace Efficiency. The Defender Catalogue No. 10, which is just off the press, shows a very complete line and price list of Combustion Appliances and Damper Regulators for the Boiler Room.

The Defender Automatic Regulator Co., 709 Pine St., St. Louis, Mo., U.S.A.

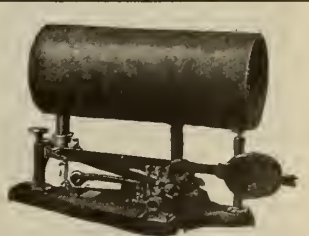
"Black Diamonds" are Precious



Save them

COAL is scarce. The supply is still limited. Scarcity means high prices. You should save every piece of this precious fuel as a measure of business economy.

Morehead Back-to-Boiler System will Save 8 to 20% of Your Fuel.



It keeps condensation out of your steam lines by returning it to the boilers while it is HOT. In a year's time you save many tons of coal. The MOREHEAD SYSTEM gives freedom from steam troubles and maintains a uniform temperature throughout the plant. Requires practically no attention. Let us tell you more about the New Improved Morehead Trap.

REDUCING VALVE PERFECTION

The "Morrison" Line

will solve the problem of steam and air pressures *Efficiently* and *Economically*

It is the ultimate valve because it does all that a pressure-reducing valve could possibly do It makes no difference how the initial pressure varies, the J.M.T. will keep the low pressure constant.

Made in sizes and with pressure ranges to suit every requirement, and sold with the well-known Morrison guarantee. We will be glad to prove our claims. Ask us.

Vol. XII.—No. 7. Publication Office, Toronto—May 20, 1919 Published Semi-Monthly $1.00 per Year

PENBERTHY

AUTOMATIC CELLAR DRAINER

OPERATED BY WATER PRESSURE

The float is built around the suction pipe—more compact and overcomes troubles of loose lever type of float.

The float instead of being round is flat on top—gives more buoyancy than round float of same diameter.

The float arms are slotted allowing float to travel the length of these slots before operating the valve which is therefore never **partially** opened or closed. Prevents wear, leakage and dribbling of water as is common with some drainers.

All working parts above water, under the floor level and accessible without disconnecting pipes or removing drainer. Foot valve provided in every drainer.

IMPROVED EJECTOR, SIPHON OR STEAM JET PUMP

The most

Modern, Up-to-Date

Cellar Drainer on the market.

FOR LIFTING OR ELEVATING LIQUIDS

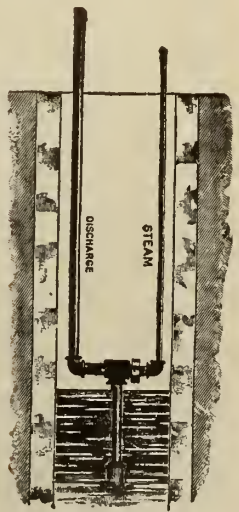
WHEN OPERATED BY STEAM

Lifts 22 to 25 feet.

Elevates 25 to 100 feet, 30 to 100 lbs. pressure.

The Penberthy Ejector is a convenient and reliable combination of **lifting** and **elevating** power and is without doubt the best device of its kind on the market.

When you buy injectors, ejectors, brass valves, cellar drainers, lubricators, etc., specify "Penberthy."



SHOWING EJECTOR OPERATING IN A WELL

MANUFACTURED BY

PENBERTHY INJECTOR CO., LIMITED, Windsor, Ont.

POOR LUBRICANTS EXPENSIVE AT ANY COST

INDUSTRIAL success is based on power. You cannot have efficient economical power unless every power unit in your plant is properly lubricated. It is poor economy to consider price ahead of quality when deciding upon the lubrication of your power plant.

Poor lubricants cost more per lubricating hour on any given dynamo or engine than good lubricants, even though the cost per gallon is necessarily higher on good lubricants. Poor lubricants often burn and wear themselves out at a provokingly fast rate.

Then, at best, poor lubricants cannot do well what they are bought to do. They are often lacking in many qualities that good lubrication requires. By using poor lubricants you materially shorten the life of expensive power units. The use of Imperial lubricants is bound to show in reduced up-keep costs. Every lubricant in our line is a uniform, scientifically and accurately-formulated one. Imperial lubricants do not vary.

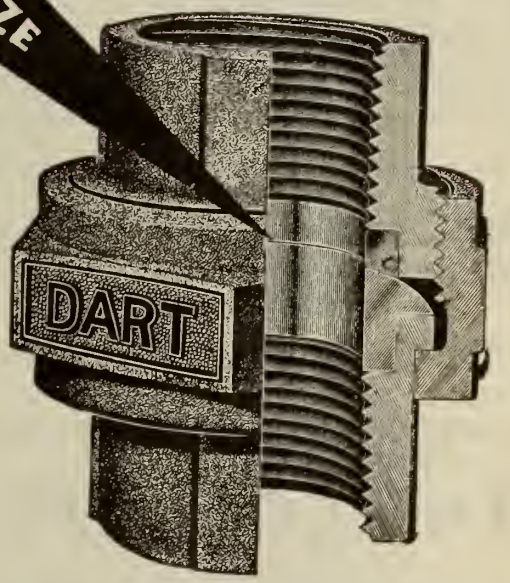
BRONZE TO BRONZE
at the Joint

WHEN THE BRONZE FACES of Dart Unions are drawn together you have a joint that is practically everlasting in its efficiency.



DART UNIONS

THE BRONZE FACES of Dart Unions never deteriorate, and the heavy iron parts are a guarantee against stretching or pulling apart.

Absolutely no leaks — no upkeep cost—no replacement cost—easily connected.

The ball-shaped seat allows for an easily-made and perfectly tight connection, whether pipes are in or out of alignment.

Dart Unions are made in a variety of styles to fill all requirements.

ORDER FROM YOUR JOBBER.

TALBOT

Contra-Flow Steam Boilers

(Equipped with Crude Oil Burners)

Cut the cost of power production because the cost of operation is cheaper than any known power producer

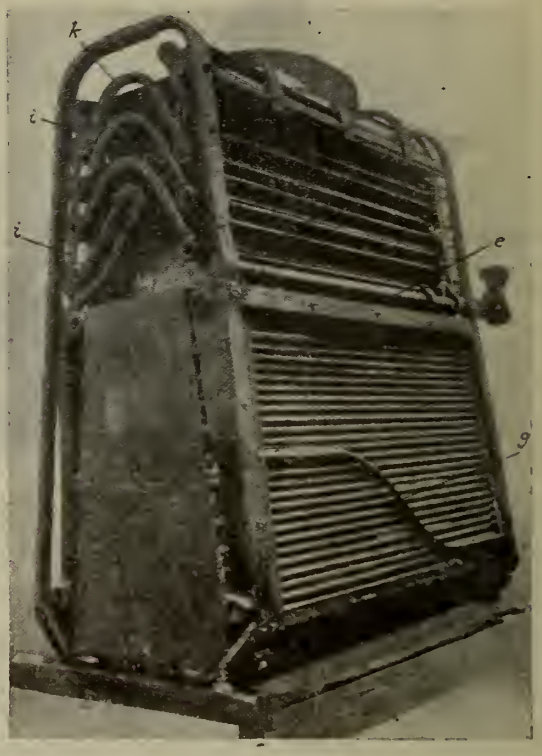
Water enters the "Talbot" near the stack and leaves in the form of steam near the furnace.

The circulation is through water tubes and is forced at a high velocity by means of a pump doing away with a water drum. By preventing gravity circulation the steam is drawn directly from the lower tubes, eliminating the steam drum. The boiler is internally fired, and hence self-contained. Feed water and fuel burners are automatically controlled to adjust the boiler to widely varying demands for steam.

Canadian Manufacturers and Sales Office:

Montreal General Tool Co., Ltd.

675 Notre Dame, Maisonneuve
MONTREAL, P.Q.



Responds quickly to sudden demands for steam through automatic control—positive circulation.

"THE COVENTRY" CHAIN DRIVES

THE ideal drive for all kinds of power transmission. In the case of the rolling mill illustrated, considerable power, large reduction of speed ratio, even flexible torque, silence and short centres are required. Note short distance between centres in front chain drive.

The QUALITY of

D. K. McLaren's Genuine British Oak-Tanned Leather Belting

Becomes More Evident As Time Rolls On

When you buy D. K. McLaren's Leather Belting you get a belting that will stand up under many years of severe service. The fact that many of Canada's Largest Power Plants are steady users and that the biggest percentage of our business is repeat orders, speaks well for the popularity of our product.

D. K. McLaren's Belting represents Flawless Backs of the hides of the choicest steers tanned by the genuine British-Oak process; the best known for preparing belts for hard service. Every bit of the hide's natural strength is preserved. Minimum stretch, minimum slippage and fewer breaks are the results you can expect.

The Right Belt in the Right Place

This illustration shows a Graton & Knight veteran in a Spartan Double Belt, 46 feet long and 8 inches wide. It is running every day in the plant of the Leroit Furniture Company, St. Louis, Mo. It has seen 4½ years' of service. This belt-eating sanding machine wore out three 9-inch ordinary belts in eighteen months. Its cost has been 40 cents a week with long service to come.

Here is punishment for *any* belt. And as usual Spartan is the belt that is game for it. It shows the right belting material in the right place. Spartan, greatest of pulley-grippers, flexible and elastic, is solving the problem of the trouble-making drive in thousands of plants. There is one answer and one reason—leather properly tanned and fabricated for a given purpose—a Standardized Series.

Write for information about Standardization as applied to Belting.

ST. CATHARINES, ONT.

Eastern Sales Office: Hall Machinery Co., Sherbrooke, Que.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

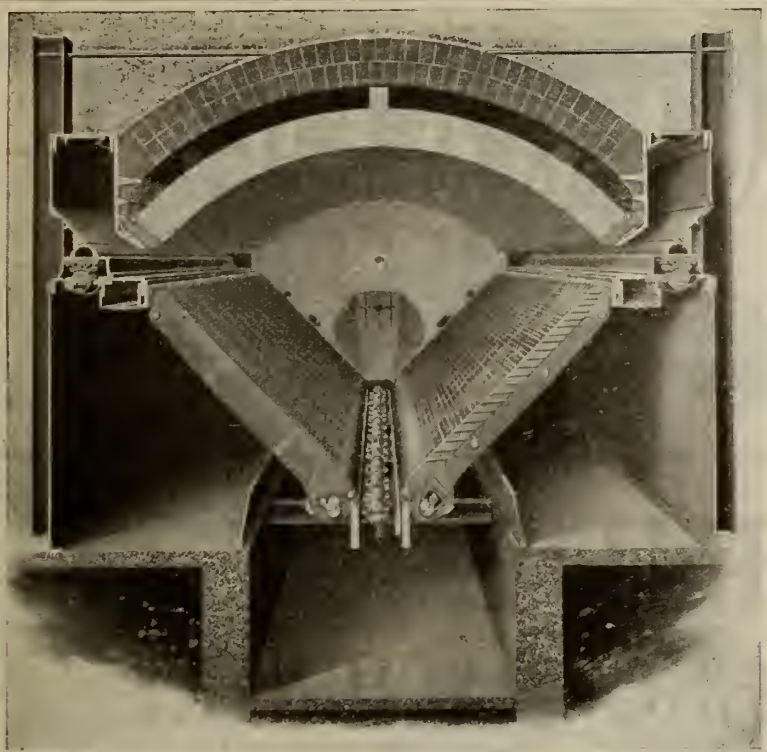
Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Shell-Bar Boico Supply, Ltd. 376 Dufferin Street Toronto

Eastern Sales Agents: Mill Supply Department, Beveridge Paper Co., Ltd, Montreal; Adolphe Huot Reg'd., Quebec



Cross section showing the construction and operation of the Murphy Automatic Furnace. As the fuel progresses downward the alternate movement of the grates ¾" above and ¾" below the surface of the stationary grates breaks up the fuel bed—prevents avalanching—keeps the grates clinker-free and advances the ash gradually to a point where it is removed by the clinker grinder.

A MISER WITH FUEL

That's how one engineer expressed it—when asked about the coal-saving characteristics of

MURPHY AUTOMATIC FURNACES

They are not only misers with fuel but they burn "any kind of fuel that has heat in it," slack, lignite, sawdust, or even refuse.

Our new illustrated catalog, HM-5, explains how the improved Murphy construction makes every heat unit work. Send for copy.

For information on the Riley Underfeed Stoker for large boilers see advertisement in last issue or send for Catalog HR5.

Quality Products Leave No Regrets

York Ice-making and Refrigerating Machinery is not made to fit the price. We have a standard of quality and service which has been maintained ever since the York Organization was started.

It is betraying no secret to say that many owners of ice-making and refrigerating plants have expressed to us, by word and letter, their keen regret at having turned down a York contract because the price seemed too high.

Price is a poor gage to use in buying such important equipment as Ice-Making and Refrigerating Machinery. Confidence is a better one. You know from your own experience that business born of confidence begets new business.

No customer can truthfully say that the York Organization ever tried to take advantage of him. It is on this basis that we have been selling our products, and it is for this reason that we have been successful.

An inquiry from you will be appreciated. You are not obligated to buy York equipment until you are satisfied as to its quality and our good intentions.

Pure Corkboard

Made in Canada

A New and Important Source of Supply

All buyers know that the sources of supply of pure Compressed Corkboard and Granulated Cork are few—too few—and the output entirely inadequate at times—an unhealthy situation for the buyers.

Therefore, you have special interest in this *new* and *important source of supply*, large in volume, fine in quality and right in price.

It offers you added *security* both as to *cost* and *deliveries*.

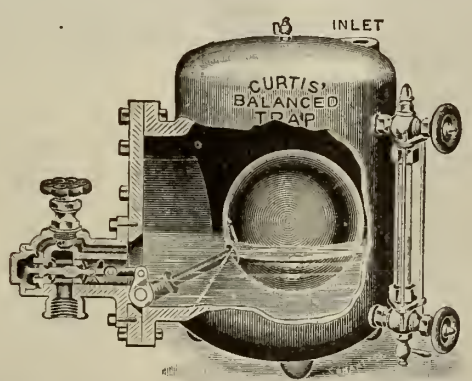
Pure Corkboard is now a necessity to the refrigerating industries, which use many millions of square feet yearly in the insulation of more than eighty per cent, of new construction and repair work.

We are prepared to handle your complete requirements, either for material only or installed in your building. Write us to-day and we will gladly give you full information and quotations.

Canadian Corkboard Company Limited

Head Office: 17 Adelaide St. East, TORONTO

Works at Port Colborne, Ont.



Five Superior Features of the Curtis

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on pressure varying from one to 250 lb.

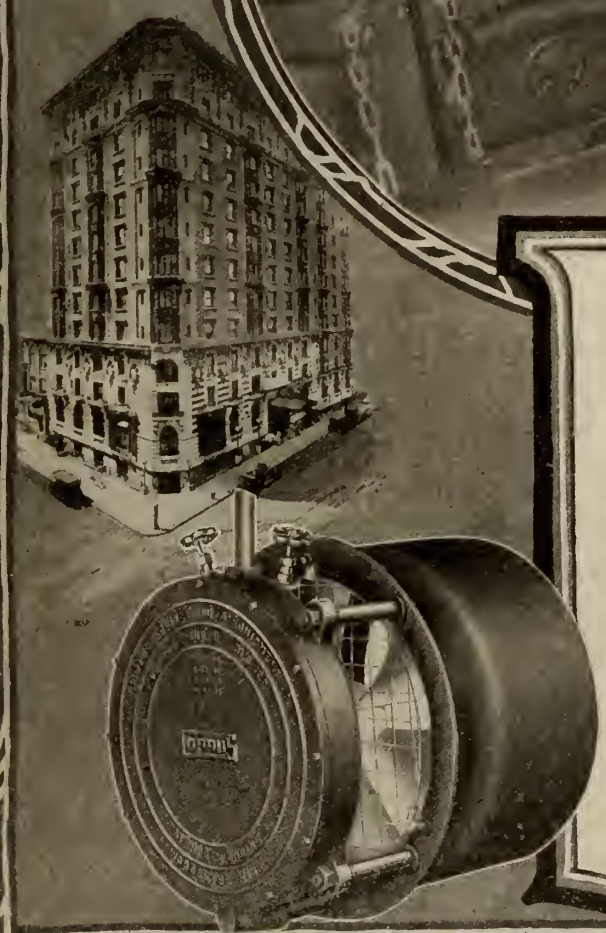
REGISTERED COPPUS U.S.PAT.OFFICE

In Hotels



This is one of the two 18″ COPPUS Blowers which have been saving money in the power plant of the Hotel Seville, New York City, for more than two years. They cut coal costs, meet peak loads quickly, keep steam pressure constant, save firemen's labor, prevent clinkering, get all the heat out of the fuel, and—an important item, run smoothly and quietly without trouble.

That COPPUS Blowers operate as effectively in hotels as in power plants of mines, mills, factories—in power plants of any sort—is emphatically proved by the fact that numerous other prominent New York hotels use blowers bearing our trade-mark. For example, Broadway, Central, Girard, Latham, Marseilles, Martinique, Shelburn, Langham, Theresa, Waldorf Astoria, etc., have satisfactorily demonstrated the money saving possibilities of COPPUS equipment.

What COPPUS Blowers have done in other plants they can do in yours. Allow our engineers to show you how **"COPPUS equipment can save you money."** Write for Blower Catalog H7.

Jones Underfeed Automatic Stoker

feeds fuel better and more economically than the best of firemen

THE JONES MODERN WAY

The "Jones Stoker" will not only effect a saving of from 15 to 25 per cent. in fuel cost, it saves labor —and it gives a smokeless stack.
The Automatic action of the "Jones" maintains a uniform steam pressure—it responds instantly to varying demands for steam.
There is a great advantage in the Jones Simplicity, no parts move in contact with the fire—this ensures long life. No losses through grates—there are none.

Dodge Mfg. Company Explains to Men in the Plant Reasons for Advertising

By G. D. Crain, Jr., Editor "Class"

THE Dodge Mfg. Company, of Mishawaka, Ind., probably the largest concern in the country making power transmission equipment exclusively, has just started an advertising campaign which will lay great stress on reaching industrial buyers through their trade and technical papers.

Melville W. Mix, president of the company, whose unique methods of securing the cooperation of the 1,500 employes of the company have attracted national attention, held a meeting March 21 to talk to the men about the campaign and to show them why it was a good thing for them.

"Conditions at present are such that advertising is bound to be of great value as a stabilizer," explained Mr. Mix, in telling about the meeting. "Business will be strengthened in many ways by the right kind of advertising at this time. We believe the campaign will put Dodge products over in fine style.

"But these things are not always understood by the men. When they see big advertisements printed in the magazines, they are likely to wonder why the money was not used in a way that would react to their benefit more directly. So we decided to anticipate anything of that sort by telling the whole story in advance of the opening of the campaign."

This was done, and more than 800 employes attended and heard Mr. Mix explain what the advertising is to accomplish. Kenyon Mix, his son, who is in charge of the campaign, showed a lot of stereopticon slides of the copy that is to appear, and the meeting resulted in the factory men being just as completely sold on the advertising idea as the salesmen had been at another meeting.

Advertisers who follow the Mix method, and take their workers as well as their salesforce into their confidence regarding their advertising methods, will get a reaction that will help to make the product as good as the advertising.

Though some national publications will be used in the Dodge campaign, the trade and technical papers have been brought into the schedule in numbers, and a total of 376,336 circulation of this character has been arranged for.

That the company appreciates thoroughly the value of specialized mediums is shown by the stress laid upon the trade publications in announcements going to mill supply dealers, who distribute the Dodge products.

"Every industrial division," it explains, "has one or more strong trade journals.

"These trade publications do not duplicate each other's circulation; they reach the technical man, the superintendent, the executive of one specified industry, because they print the matter that he must know to operate his business at a profit.

"Someone in every industrial plant reads the trade paper of that industry. It is a part of his job to keep informed.

"We found it necessary to advertise in 31 trade papers to reach the thinking men of 20 industries. And we have contracted for full-page space in every one of them."

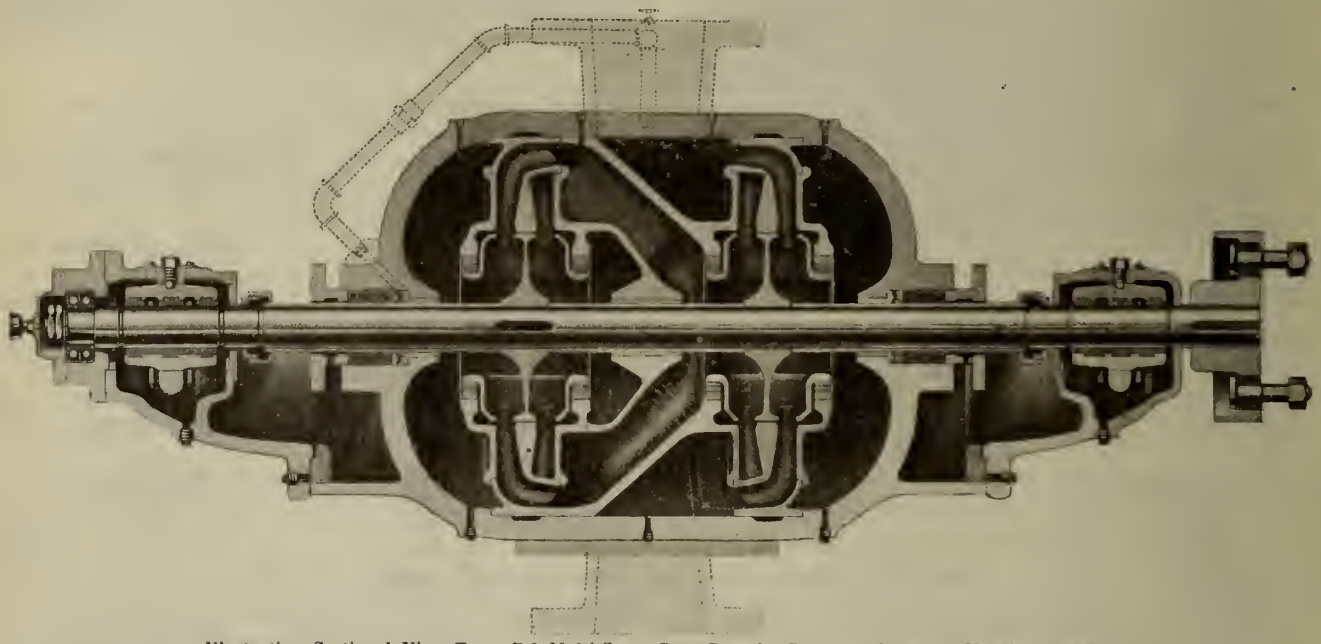
"Read some of these pieces of copy," it is suggested. "Notice particularly that the advertisement to appear in a publication circulated to the rubber industry tells how Dodge products are adapted to rubber mills. Notice how the copy which will be read by a paper mill engineer describes how Dodge products cut the cost of production in a paper mill."

This is, of course, one of the big advantages of trade and technical advertising—the opportunity to talk to the trade buyer in his own language, and to discuss with him the application of product to the special problems of his industry. This is the advantage that is missed entirely by the advertiser who uses merely general circulation, and consequently is compelled to talk in general terms.

REES RoTURBo

Pumping Machinery

Is in use all over the World in Waterworks, Mines, Power Stations, Irrigation Works, Pulp and Paper Mills, Salt, Chemical and General Industrial Plants where highest efficiency, reliability and the best class of Engineering are demanded.



Illustrating Sectional View Type, B.2 Multi-Stage Rees Roturbo Patent Pressure Chamber Pump.

REES RoTURBo Pumps provide a high and sustained efficiency over a wide range of duties. This means a very noticeable saving in power costs.

The Self-Regulating feature of RoTURBo design is responsible for this saving, and this same feature protects your Prime Mover from overloads on a decreased pressure head, eliminating expensive delays and costly repairs.

Our RoTURBo Pump and Condenser Catalogues, full of valuable information, are yours for the asking.

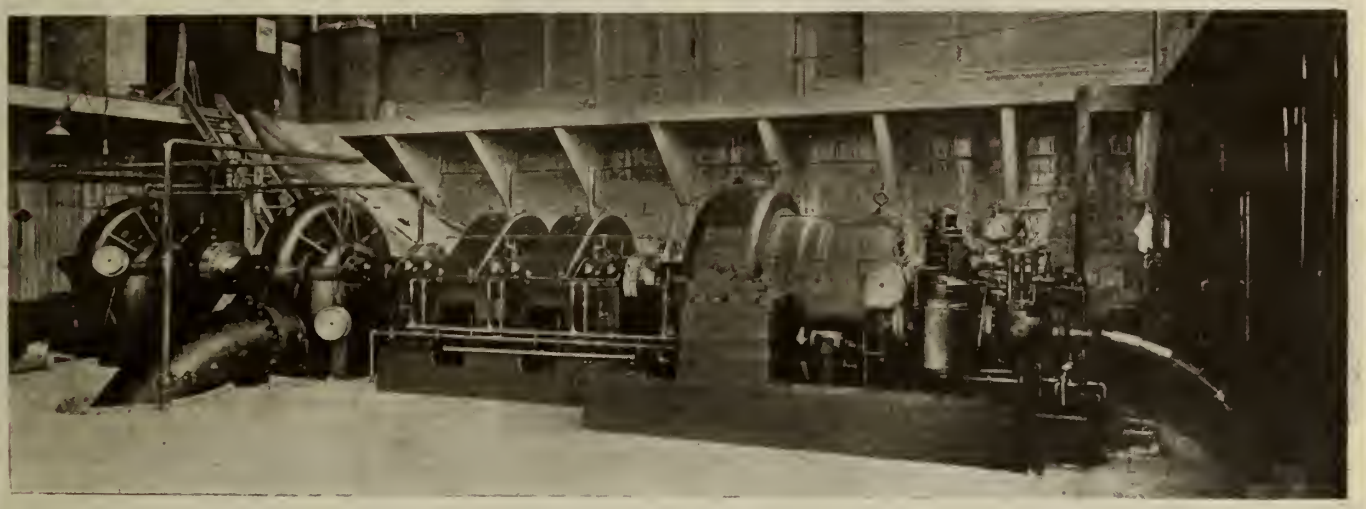
POWER HOUSE

Established 1907 — Published Semi-monthly

Main Pumping Station Toronto Waterworks

Modern Equipment and Recently Completed Extensions Result in Efficient Plant of High Duty

By W. F. SUTHERLAND, Editor Power House



THE rapid growth of municipally owned utilities is indicative of the expansion which has taken place in the size and activities of Canadian cities. From a capacity of 50,000,000 gallons prior to 1913, the Toronto waterworks has grown until a capacity of about 200,000,000 Imperial gallons per twenty-four hours is available when required. This increase has necessitated very extensive alterations throughout the whole system, the installation of new filter units on the island, new mains, and a complete reconstruction of the John Street pumping station.

Present Arrangement of Waterworks System

Water is obtained from Lake Ontario through intake pipes running south from Toronto Island and is pumped on to filter beds. Two systems are now in use, the slow sand filter and later units operating on the drifting sand principle. These latter units are able to filter unusually turbid water without clogging of the filtering material, and without the use of large setting tanks and coagulating basins. The coagulant, sulphate of aluminia, is introduced into the raw water in the suction well. This water is then pumped onto the filters. The sand-bed is composed of fine sand, 9 feet deep, laid on a bed of gravel 9 in. deep, and the action of the incoming water causes the upper part of the sand bed to drift across the water being filtered. The bulk of the impurities, together with a part of the drifting sand, is swept out. The lower portion of the sand-bed which remains stationary, removes the remaining impurities.

NEW BOILER ROOM SHOWING STOKERS AND COAL CHUTES.

From the filter plants the water is conveyed to the city proper under the Bay through a tunnel 8 feet, 6 inches high, and exactly a mile long. This tunnel is about 100 feet below the level of the lake, and the water rises from it through a shaft 10 feet in dia-

VIEW IN ASH TUNNEL. THIS PICTURE WAS TAKEN WHEN THE PLANT WAS UNDER CONSTRUCTION.

meter and of the same depth. From this suction well the pumps draw their supply and provide sufficient head for distribution throughout the city, except to the northern section, where a boosting station, the High Level Pumping Station, is provided.

General Arrangements

As will be seen from the accompanying plan and cross-sections, the main pumping station is divided into several units. Two 15,000,000 gallon high duty pumping engines, built by the John Inglis Co., are installed, and form one of the earlier portions of the plant.

On the advent of Hydro power four Boving centrifugal units, driven by Westinghouse motors, were installed in a separate room. These pumps are rated at 13,000,000 gallons each, and the motors are of the synchronous type, a jaw clutch being provided so that the pumps may be disconnected and the motors run free for power factor correction.

A high pressure pump room houses two Westinghouse Parsons turbine units, driving turbine pumps, made by the Caledonia Iron Works, of Montreal. These two-stage pumps serve to boost the pressure on the high pressure fire mains, laid in the down town district to 300 lbs., on the advent of fire in the down town section of the city, and are only operated when this occurs. The casings of these pumps, it is interesting to note, are of cast steel. Each of these pumps has a capacity of 5,000,000 gallons per 24 hours.

Turbine Pump Room

The portion of the plant immediately to the west of that housing the reciprocating units is of recent construction and contains the De Laval turbine driven pumping units.

The turbines are of standard De Laval construction, and are designed for a steam pressure of 150 lbs. and a vacuum of 29 inches, the normal speed being 3430 r.p.m. Each is direct coupled to a speed reduction gear having a ratio of 33 to 197, so that the pump shaft rotates at a normal speed of 575 r.p.m., and the steam supply pipes to these units are 4½ in. with 36 in. exhaust to standard Wheeler surface condensers, so placed that all the water delivered by the pumps passes through it as cooling water.

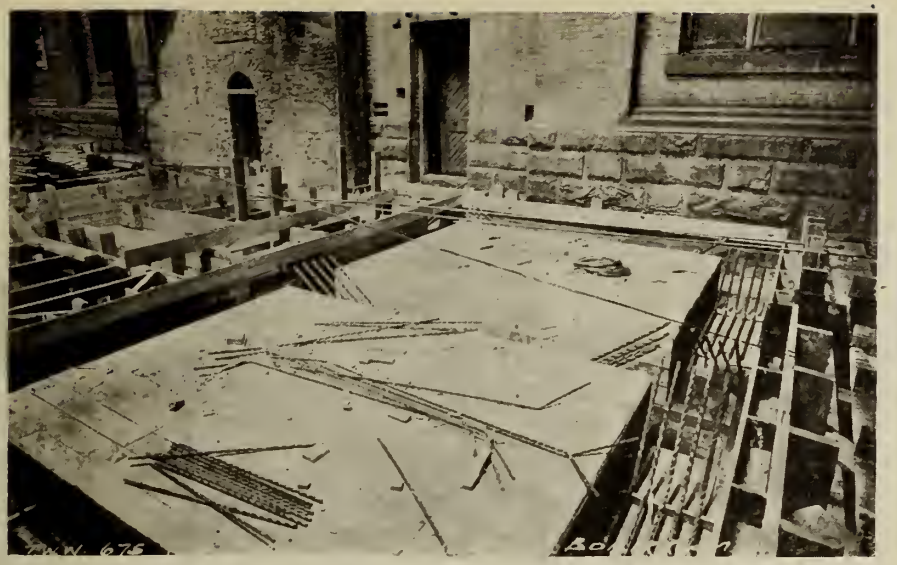
The vacuum pumps are Rotex pumps, built by the C. H. Wheeler Co., and are driven by 7x7 in. engines exhausting into the steam turbines at about the middle stage, doing further work there. Two single stage double suction pumps are connected to each unit, the two pumps being piped together in series. At a speed of 575 r.p.m. each unit delivers 20,000 U.S. gal. per min., equivalent to a pumpage of 24,000,000 Imperial gallons per 24 hours.

The DeLaval Company guaranteed a duty of 141.5 million foot-pounds per thousand pounds of steam, and on test a duty of over 150 million foot pounds was obtained, a remarkably high efficiency.

The two motor driven units are also of 25,000,000 gallon rating, and are two stage pumps built by the John Inglis Co., Toronto. Each pump is driven by a 1,500 h. p. wound rotor induction motor of Westinghouse make.

It may be mentioned that in arranging the suction pipe for these five units it was necessary to dig a trench 20 feet deep and about 8 feet wide in rock. Much trouble was experienced from water seepage, and it was found necessary

TURBINE PUMP ROOM.



THE FOUNDATIONS FOR THE NEW BOILER SETTINGS ARE OF REINFORCED CONCRETE. THIS ILLUSTRATION SHOWS THE REINFORCING BARS AND FORMS.

to instal two 12 inch pumps to control it.

The Boiler Room

The new boiler room presents many features of interest and has a greatly increased capacity over the old one now torn down. Much of the older equipment is incorporated in the new one, nine of the sixteen boilers having come from the old boiler room.

The boilers are all of the water-tube type and are of 300 boiler horsepower nominal rating. Six Heinie boilers are installed, fitted with Chicago & Green chain grate stokers. The Canada Foundry Co. supplied seven Atlas cross-drum boilers, which are fitted with Chicago and Fulton stokers, and the John Inglis Co. supplied three Erie City boilers, these latter being fitted with Bennis chain grate stokers, made by Bennis, of Little Hulton, Bolton, Eng.

The Fulton stokers are part of the new installation and are fitted with water backs, as may be seen from one of the accompanying illustrations, which shows the stoker in the course of erection.

The boilers are all fitted with draft gauges made by L. M. Ellison, Chicago, and soot is blown by compressed air. Operating steam pressure is 160 lb.

Chimneys and Breeching

Two Custodis Radial brick chimneys are installed, one for each bank of boilers. These chimneys are 96 in. by 160 feet high, and are lined with firebrick to a height of 50 feet. The breechings at the chimneys are 8 feet, 6 inches, by 5 feet in size, and throughout their length are lagged with heat insulation, supplied by the Armstrong Cork & Insulation Co.

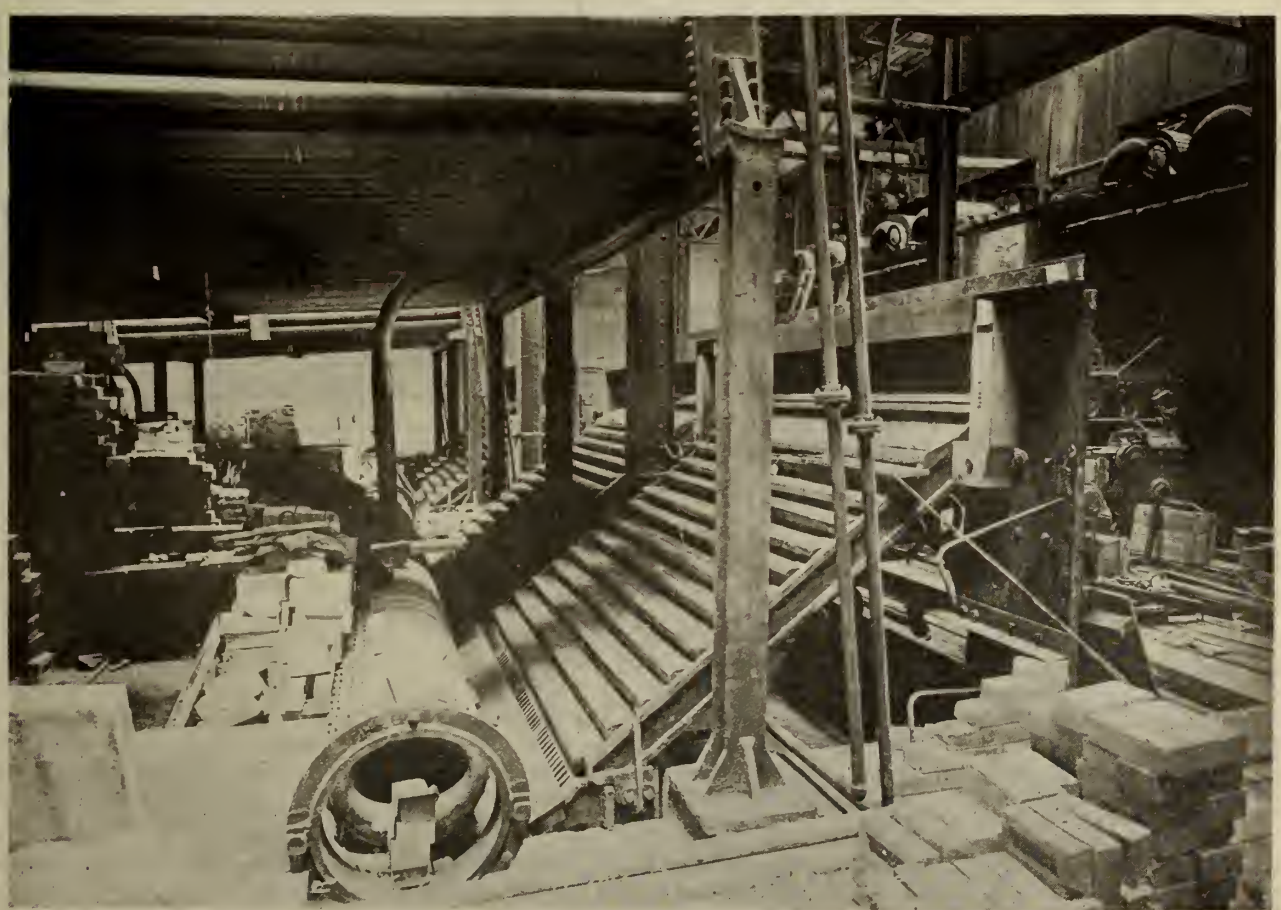
Steam Piping

The steam piping is fitted throughout with Van Stone joints and Crane valves. The main headers are 12 in. diameter, and the steam mains throughout are lagged with insulation supplied by the Armstrong Cork & Insulation Co., Toronto. As an illustration of the excellent design encountered a metal legging is laid on over the heat insulation for mechanical protection.

The bends and pipe work were all supplied by Purdy-Mansell, of Toronto, and it is worth noting that the workmanship in the making of the pipe bends was such that everything came together without any fitting being required on the job.

Feed Water System

The feed water system presents some features of unusual interest and in some



FULTON STOKERS UNDER ATLAS BOILERS. THE ILLUSTRATION GIVES A GOOD VIEW OF THE WATER-BACK.

respects differs from the arrangement usually found in plants for power generation.

Very little exhaust steam is available from station auxiliaries since the major portion of such apparatus is driven by or is a part of the main pumping units. Each of the two large reciprocating units are fitted with feed pumps, barrels and plungers, the plungers being driven from a yoke off the main plunger crosshead. The feed water pumped by these units, and taken from the city water supply, passes through a closed heater fed with exhaust steam from the low pressure cylinder of the unit. The exhaust steam, after passing through the heater, is condensed in a surface condenser, through which all the water pumped by the unit passes. The condensate from these units is not used for boiler feeding, and thus no difficulty is encountered through oil.

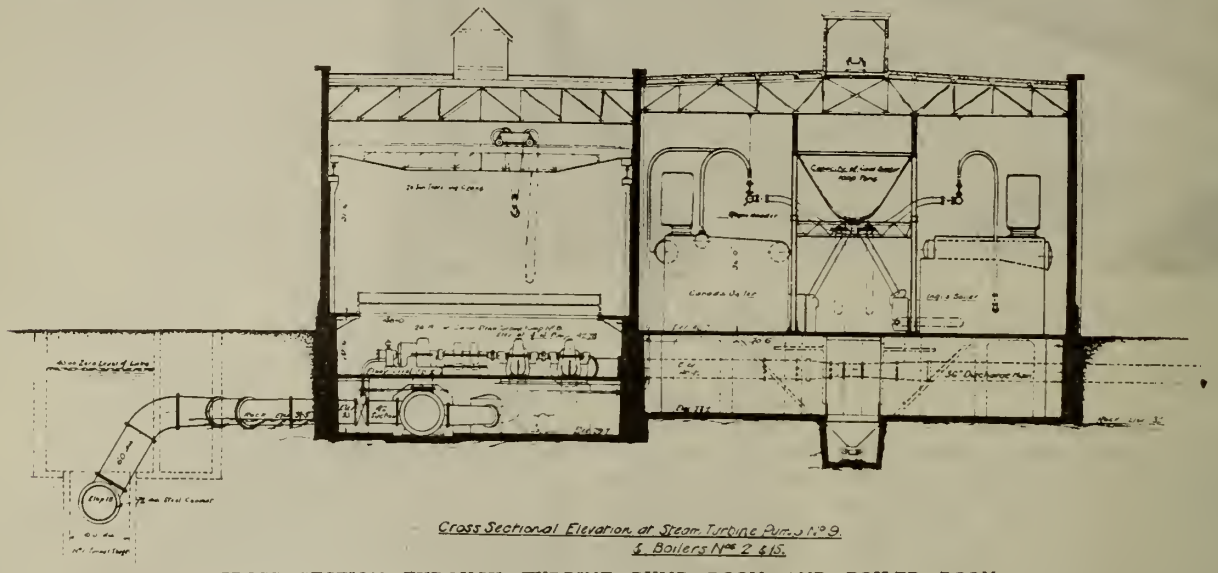
Attached to each of the three 24-million gallon turbine driven units is a Goulds triplex plunger pump, driven off the end of the main turbine shaft by silent chain. These pumps have plungers 3½ inches diameter by 6 inches stroke, and serve to pump the condensers to which they are attached into the feed mains. The surface condensers in this case are also cooled by water on its way to the turbine pumps.

The pumping of the feed water by means of feed pumps attached to the main pumping units effects a considerable economy, as the high efficiency of the large engines and turbines is thus utilized.

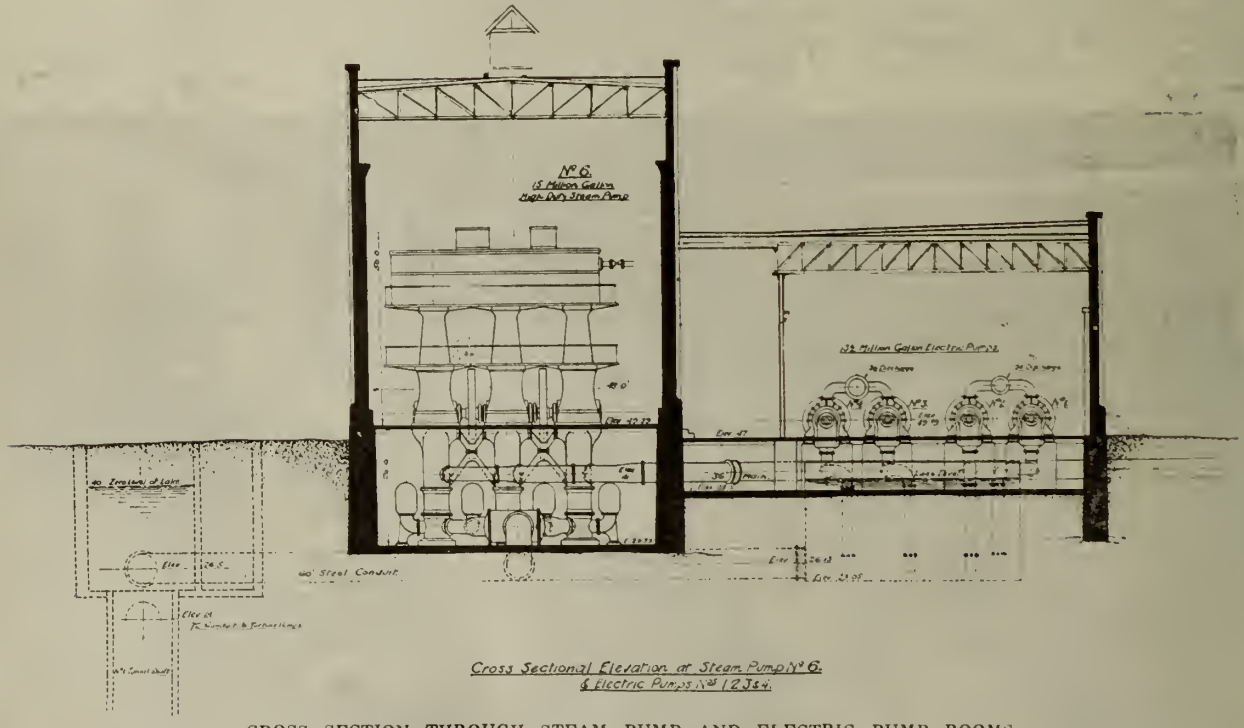
For auxiliary use a 5x12 inch duplex Northey pump is kept in reserve, and in addition to this stand-by pump a Penberthy 2 inch injector is provided on the feed line, so that if no pumps are running sufficient feed may be obtained to keep the plant running.

A standard closed type feed water heater built by F. B. Kelly & Sons, is also provided for use when required.

The main feed line forms a loop on the boiler room floor, at the rear of the boilers, and dropping below this level into the basement at the ends of the two banks of boilers. The main feed line is of 4 inch pipe, and the risers are 2 and 2½ inch.



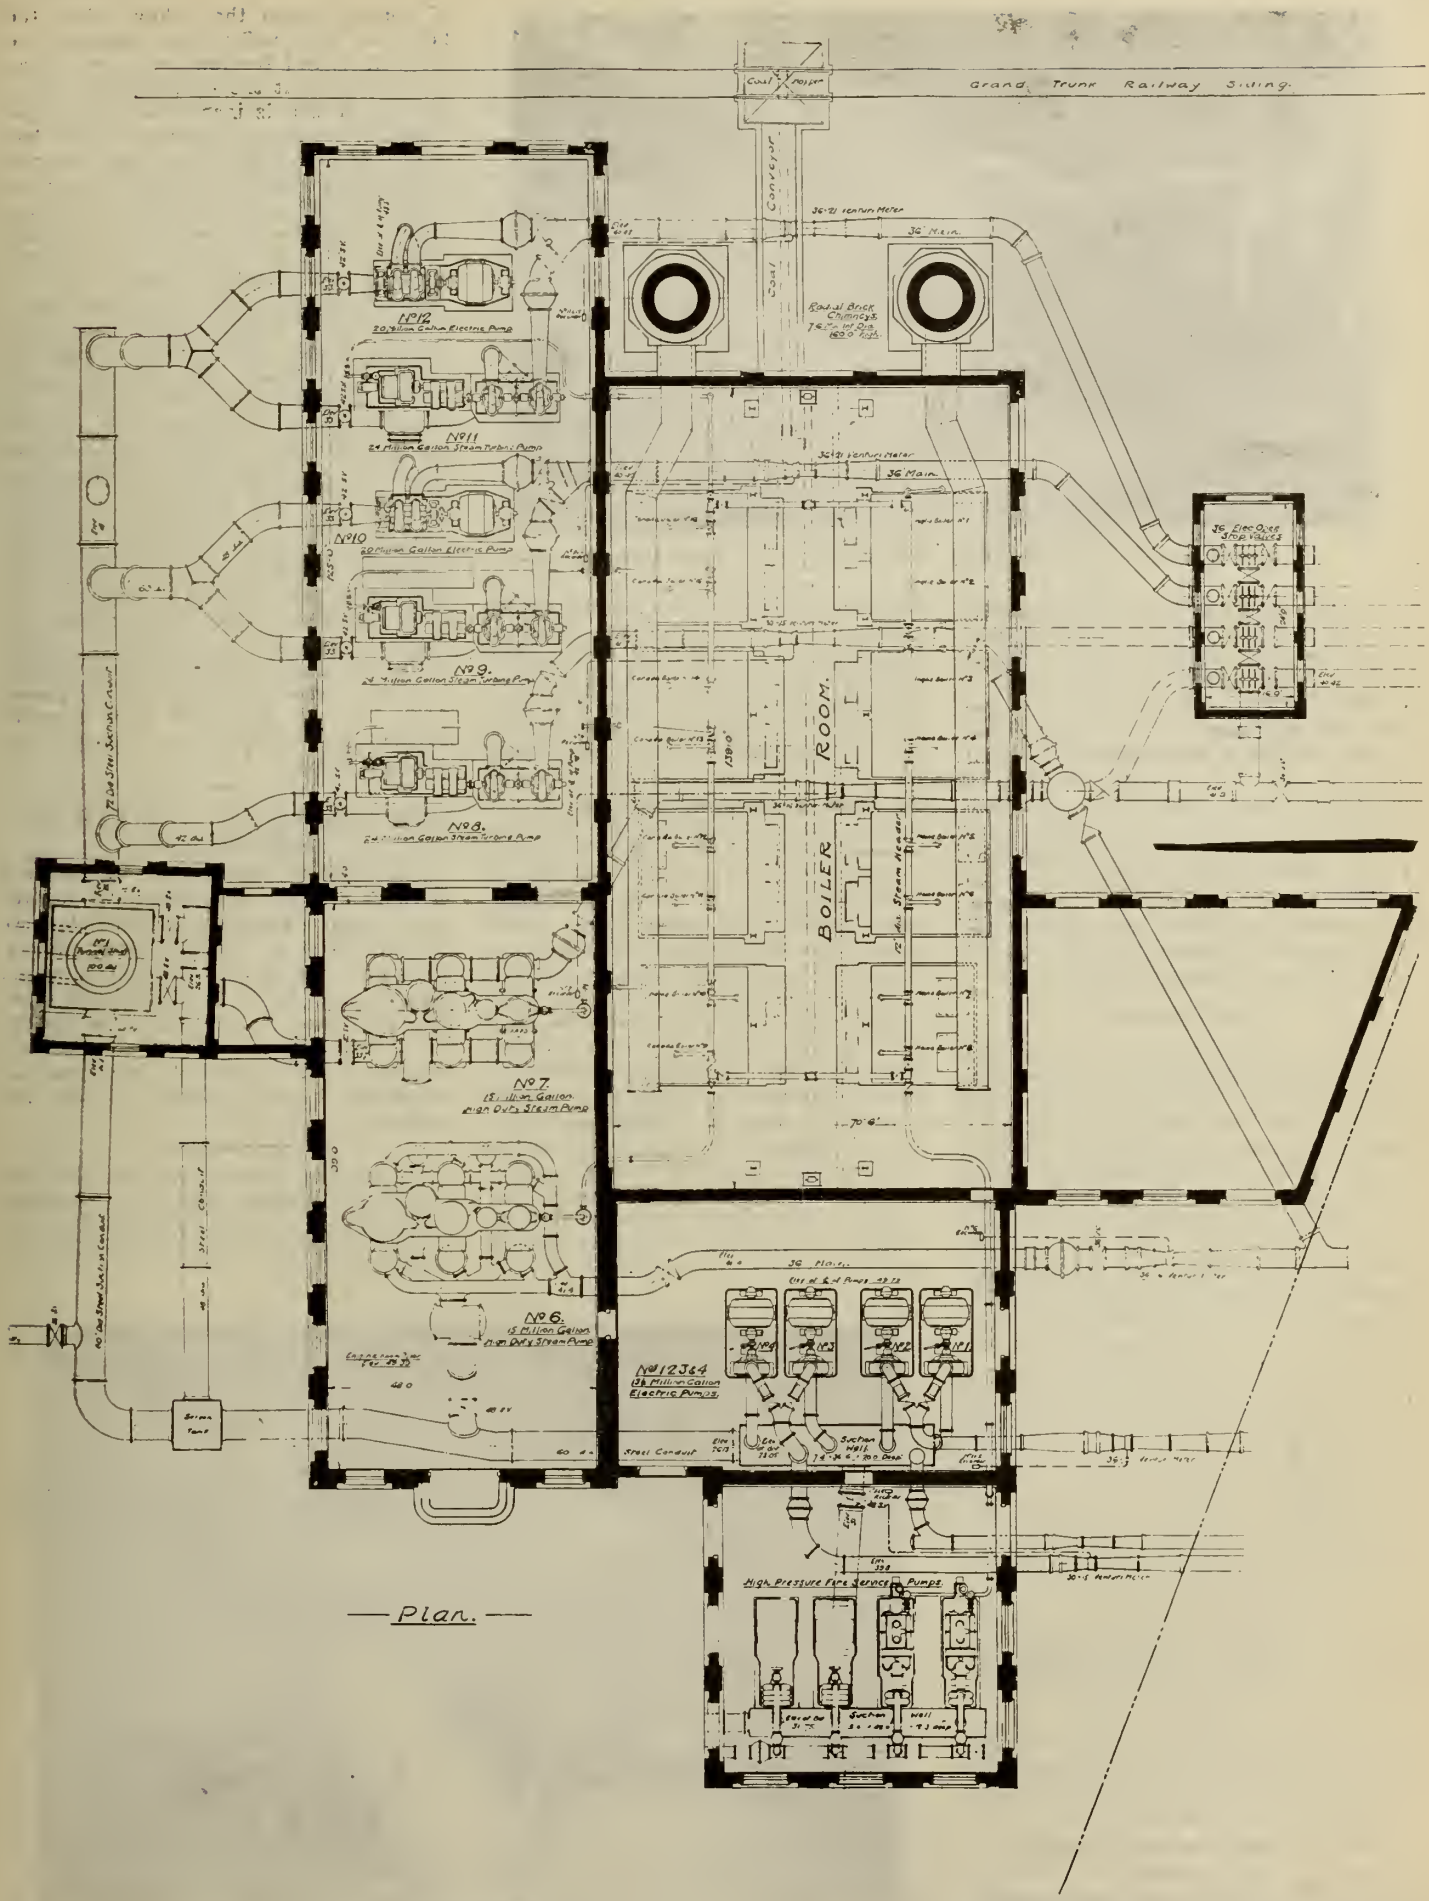
CROSS SECTION THROUGH TURBINE PUMP ROOM AND BOILER ROOM.



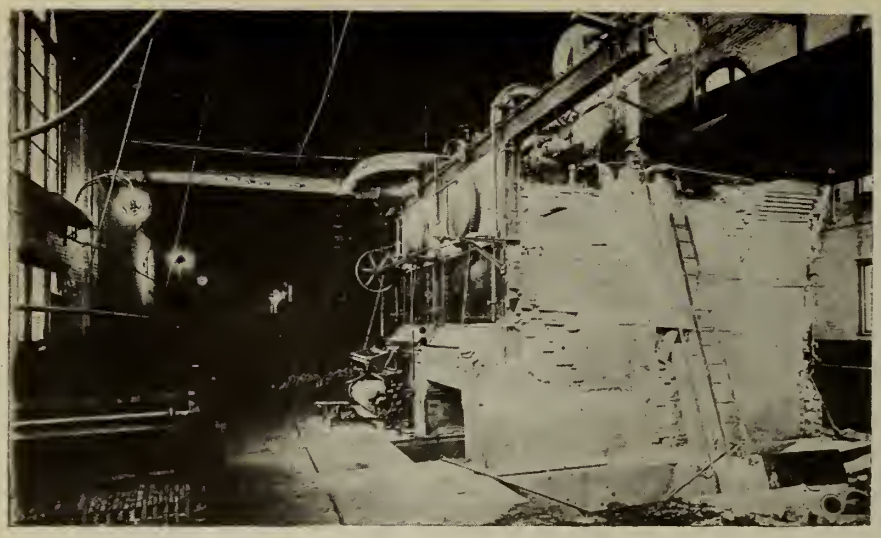
CROSS SECTION THROUGH STEAM PUMP AND ELECTRIC PUMP ROOMS.

Ash and Coal Handling

The coal and ash handling system at this plant well repays considerable study, and the accompanying line drawings give an excellent idea of its arrangement. Coal is dumped from the cars into a hopper, and from the hopper is fed into a sixteen inch belt conveyor, driven off the main bucket conveyor through a clutch by means of transmission chain. At the hopper pro-



PLAN, THE JOHN ST. PUMPING STATION, CITY OF TORONTO WATERWORKS.



VIEW IN OLD BOILER ROOM WHEN BEING DISMANTLED

vision has been made for a coal crusher, not yet installed. From the belt conveyor the coal drops through a chute into the bucket conveyor, and is elevated to the bunkers. The bucket conveyor runs the full length of the boiler room, on top through a monitor, over the coal bunker, and at the bottom through a conveyor tunnel below the ash chute level. The coal is tripped into the bunker by means of trippers located at the proper points, and the upper run of the conveyor has an automatic resetting mechanism for placing the bucket lips in the proper position relative to one another for the descending flight.

Ash Removal

The ash pits under the chain grates have inclined bottoms and are fitted with heavy iron doors for ash removal. Both the pits and ash doors are lined with fire brick and a sprayer is provided in each pit for wetting down the ashes as they are pulled. The ashes are raked out and fall through iron bar gratings of about 2¾ inches mesh into an ash chute, which feeds them directly into the bucket conveyor. The gratings mentioned extend the full width between boiler settings and prevent any large clinkers from getting into the conveyor and causing trouble. Between the gratings checkered steel plate flooring is installed. The ashes are drawn up by the bucket conveyor to the end of the bunker and are tripped into a separate compartment walled off from the coal storage by a concrete bulkhead. The bucket conveyor is driven by means of a twin cylinder steam engine with two 4x6 inch cylinders, and located at one end of the upper horizontal flight. The bunker is of the steel plate suspended type, and is lined with concrete. When full it holds 1,000 tons of coal.

The conveyor system was built by the C. W. Hunt Co., New York, and the bunker by Jeffry Mfg. Co., New York.

EFFICIENCY IN BELT DRIVES

By D. Street

In almost every factory and machine shop a certain amount of power is wasted in transmission through driving belts, the percentage of loss depending on the attention paid to the matter. Slipping, the trouble most frequently encountered, is common to all classes of belting, and generally speaking the remedy applied is to cut and tighten, or "take up" the belt so that it will run free from slackness with a better grip of the pulley; but probably more belts are broken and prematurely destroyed in this way than by actual use, not to speak of the additional load thrown on the engine and the consequent waste of power. To overcome slipping, many engineers incline to the principle of using belts wider than is actually necessary. This permits a heavier load to be carried, but when the practice is generally adopted all over a machine shop with fifty or more belt drives expense is materially increased There is, however, a growing tendency to run belts slack, as not only is friction thus reduced and the life of the belt increased, but no power is wasted and the strain on the prime mover is considerably reduced. Immediately the tension is reduced the friction is proportionately lessened. Further increase of the arc of contact round the pulley (after the belt has been sufficiently slackened to have no initial tension) will not lessen the friction, but the load-carrying capacity of the belt is increased. As an example in many engineering shops it has been found that cuts 50 per cent. heavier can be taken on lathes where the arc of contact has been increased from 180 deg. (with a tight belt) to as high as 220 deg. (with a slack belt) and in one instance with a corn-crushing machine the increase in output was over 50 per cent. To permit of driving belts being run slack a proper belt dressing should be employed. Many belt dressings rely almost entirely on their capacity to "stick," due to the inclusion of rosin or tar in their composition, but others take the form of a non-sticky preservative or belt food free from acid or alkali action, which is absorbed into the belt, rendering it pliable and highly effective, and at the same time protecting it from the effects of moisture, dryness, or chemical fumes. Such a preparation properly applied tends to give belts a velvety cling through the setting up of a vacuum suction between the belt and the pulley face, and will permit of slack running without fear of slip, even under the heaviest loads.

BRITISH LENSES INSTEAD OF GERMAN ONES

The English factory of the famous German firm of Zeiss, which is located near London, has been acquired by two British firms of optical lens makers. The war has proved beyond a doubt that English firms are capable of turning out lenses far surpassing in quality the German ones. Before the war it is estimated that about 95 per cent. of the lenses used in the U. S. were imported.

"I consider POWER HOUSE the best in Canada, because it touches on local power plants as no other paper does for the engineer." — Mr. Greenwood, Hamilton.

OLD BOILER ROOM REMOVED AND EXCAVATION MADE FOR NEW SETTINGS.

Boiler Troubles; Their Origin and Remedy

In This Article the Author Discusses the Many Ills That the Steam Boiler is Heir to and Deals With Preventative Measures and the Proper Remedies for Faults Which May Occur

By T. H. FENNER, Associate Editor

ALTHOUGH a steam boiler is a very solid looking piece of machinery, it is liable to a variety of troubles, most of which are from causes extraneous to its construction.

Different types of boilers exhibit different effects from similar causes, depending on structural features. It is proposed to mention some of the more usual defects, their prevention and remedy. While it is true that these subjects have been treated by many able writers, it is evident that there are many people interested in boilers that these writers have not reached, so that this article may not be superfluous.

Pitting

Very often a brand new boiler is affected by this trouble before it is ever put into service. Boilers that are used intermittently, with varying periods of idleness, are especially susceptible, but pitting is found under all sorts of conditions. In horizontal return tube boilers it usually attacks the tubes and shell above water line. Water tube boilers of the Babcock type will show it in the top drum, while vertical fire box boilers will develop pitting above the water line usually.

Pitting is a local oxidization, and takes the form of small blisters, under which the metal is eaten away, forming a conical hole, very much as a drill would remove it. If not checked it will eat right through the metal. In a new boiler, where the mill scale has perhaps not been thoroughly removed, and the boiler is left standing in the setting for a long while before being used, pitting is very likely to occur. A boiler left standing partially filled with water, is a good subject for pitting, while boilers being fed with very soft water are often found to be well pitted after some time of service. Pitting is one of the most insidious evils we have to combat in boiler maintenance, and is well worth a thorough examination.

Pitting in all cases is an electrolytic action, caused by the presence of metals having different chemical compositions, being immersed in water, which acts as an electrolyte. In other words, the boiler, with its working level of water, is a big cell. The shell of the boiler becomes one pole, the tubes the other, and discharge occurs from one to another, through the medium of water. The same action will take place if the boiler is empty but damp. Temperature and pressure affect the action, and there are various local effects, which are too complicated to enter into here. Iron is soluble in water, and combines with it, forming ferrous hydrate. In the presence of oxygen the ferrous hydrate is oxidized and precipitated in the form of rust. It is here that the pitting takes place.

How to Detect Pitting

It is important for the engineer in charge of a boiler to know when pitting is taking place as soon as it starts, in order to take steps to counteract it. Pitting is one of the easiest things to detect when its characteristics are known, and it is also easy to check if taken in time. In spite of this there are hundreds of boilers yearly going gradually to uselessness through this very cause. The number of boilers met with in the writer's personal experience, which were suffering from more or less advanced cases of pitting, was surprising.

The earliest indication of pitting is a very small discolored spot on the surface of the metal. This may be so small as to pass unnoticed unless the examination is thorough. Scraping with the point of a knife would result in the oxidized metal falling away in a powder. At a little later stage the oxidized metal will form a small blister or bubble, underneath which the action is continuing. The appearance cannot be mistaken, but scraping will prove it beyond a doubt. Once detected preventive methods should be taken at once.

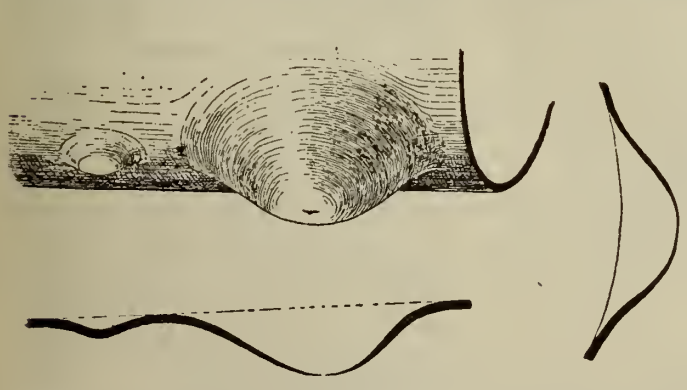
Prevention of Pitting

The time to prevent pitting is before any signs of it appear. This may sound peculiar, but it is just as true as the prevention of disease in the human body. Nowadays, people don't wait until they have to cure typhoid. If there is any likelihood of contracting it they hie themselves to a doctor and get a lot of serum injected, which makes the body taboo to the migratory germ.

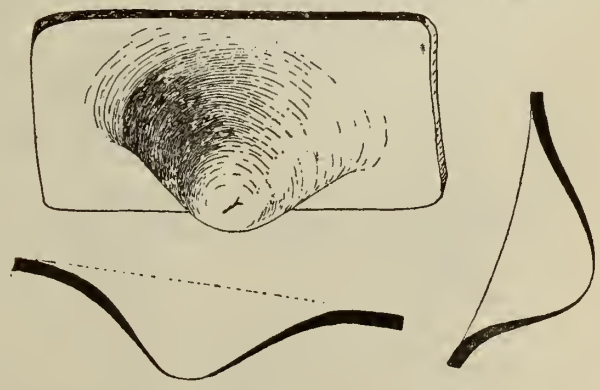
We will take the case of a new H.R.T. boiler, just erected, and the brickwork built up.

The first thing to do is to get a man inside with a good stiff steel wire brush, and get him to brush down all the metal surfaces he can reach till he has got to the metal itself. that is, until all surface scale and dirt has been removed. The surfaces he can reach will be the shell of the boiler above the tubes and, to probably, the second row of tubes down from the top. The stays and both heads can also be treated. If the boiler has a front manhole he can do a good part of the shell on the bottom, which is a good thing, not for the prevention of pitting, but in the interests of clean surfaces. When everything removable in the way of mill scale, steel chips, borings, etc., has been cleaned out, according to the man doing the job, the chief or second should go in the boiler and satisfy himself it is really so. I have seen chippings and boilermakers' washers getting in the blow-down pipes of new boilers, after they had been in service some time, and the man in charge wondering where they could have come from.

The boiler being clean, get the hose on and wash it down from the top until the water running off at the bottom is absolutely clean. The next step is to dry it, and the simplest way to do that is to close up the bottom manhole, take a small quantity of unslacked lime, and suspend it in a pan either on top of the tubes, or down between the centre rows. Then close up the top manhole and leave it for a few hours. The unslacked lime will absorb all the moisture and leave the



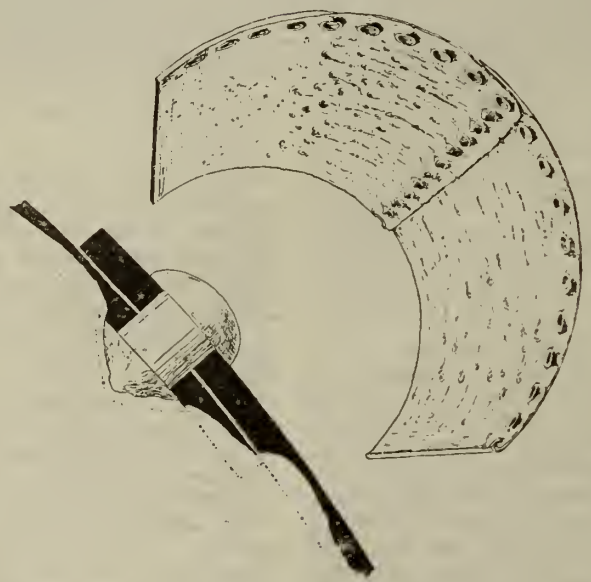
EXAMPLES OF BULGED FIRE PLATE.



SHOWING DRAWING DOWN OF METAL.

tubes and shell quite dry. After opening up again, get some good white zinc, and mix it with coal oil until you have a thin white paint. Don't use boiled oil or any other oil but coal oil.

Get your man inside with the paint brush and instruct him to paint the shell and heads from the level of the top row of tubes, and all the stays. Work your paint well in, so that it covers every particle of surface, but has no lumps. Let your paint have time to dry, and when it is completely dried up put on the top manhole. Slack back a safety valve or any joint you like above the level of the boiler, and fill the boiler slowly until the water runs out of the valve or joint. Your boiler is safe that way until you are ready to light up, and the chances of pitting taking place are remote.



EFFECT OF CORROSION

It is the boiler left standing partially filled that is the most exposed to pitting. Either fill the boiler full up, or have it empty and dry if it has to stand. The British Admiralty follow the plan of cleaning their boilers out thoroughly, and leaving them closed up with the pan of unslacked lime to dry them out.

Suppose your new boiler is in service, and the water begins to show red or rusty looking. Open the drain on the bottom of the water column, and give it a good, long blow. Then blow your glass through, and see if the water comes back rusty. If it does after several blows then you need to treat the boiler to stop it. Mix up some lime and water, until you have a very thin whitewash, about a bucketful, and put it in the boiler through the injector or soda cock on the feed pump. Do this every second day, and in a few days the rust will disappear. The lime will form an almost imperceptible coating over the surfaces, and prevent the rusting.

If pitting commences in a boiler that has been in service for some time, the same methods can be employed. However, in this case, the labor involved will be much heavier. It will be necessary to carefully examine the individual pittings, and clean them out with the point of a three-cornered scraper, or a round file ground to a point, and work at them till the bright metal is plainly seen. Look out particularly for the top row of tubes, for that is where the attack is most developed, and because of the thinness of the tube wall, the easiest to succumb. Use the paint treatment on shells, heads and stays. Use the milk of lime while the boiler is working, and apply it daily until you see the influence of the lime in the gauge glass. Open the boiler up as frequently as practicable, and note the appearance of the pit marks. Care and vigilance will prevent any further spread. I have seen some pretty bad cases stopped in this way, but it is to be noted that pitting should never be given the chance to get bad. Horizontal return tube boilers that are opened up monthly should be examined carefully at each cleaning, and the faintest indication should be noted and steps taken to stop the spread.

Boilers of the internally fired type need to be examined closely on the furnace sheets or tubes, at about the line of firebars, for pitting. Care must be taken when using the white zinc and coal oil paint, not to apply it to a heating surface, as it is not a conductor. However, it can be used on furnaces below the line of firebars with safety. It is a good plan to use it in the steam drums of B.&W. boilers as an additional precaution to the zinc plates used to protect them. These zinc plates are in general use in marine types of boilers, but are practically never employed in the H.R.T boiler.

Grooving

Grooving is another form of local erosion which is hard to prevent and remedy after discovery. This trouble is not very frequently met with in the H.R.T. boiler, but is only too often met with in the locomotive and vertical firebox type. It is a case of ordinary corrosion aggravated by the natural movement of the boiler under working conditions. The place it is usually found is around the O.G. and mud ring of vertical firebox boilers, crown sheets of locomotive boilers, where they join the side sheets, and, occasionally around the circumferential seams of horizontal boilers. Where a dome is pitted on a boiler it is well to look for grooving where the flange of the dome is riveted to the shell.

Grooving is caused by the scoring action of the water, acting on a joint that is to some extent opening and shutting. The most obvious case of this kind is the dome already spoken of. In this case it is the action of the steam instead of water, but the principle is the same. It is especially noticeable in cases where the shell of the boiler has been completely cut away under the dome, and there are no direct stays from the head of the dome. In this case grooving almost surely develops. Where this trouble is very apparent, examine the design of the boiler, and ascertain if it can be stiffened by additional staying, which will relieve the joint to some extent. If a circumferential seam, it may be due to defective caulking in the first place, and if not very much advanced, may be helped by chipping the edge of the plate inside the boiler, till past the groove, and recaulking in a proper way. Fortunately, even in bad cases of grooving, we can call in the aid of electric welding, which will build up the wasted metal to its original and greater strength if required. If all boiler joints were caulked on the inside wherever possible, there would be fewer cases of grooving. Leaky seams will develop grooves by the pure cutting action of the steam or water leaking through. That is why the smallest leak around a boiler shell should be stopped as soon as discovered, or carefully marked and attended to when shut down. Here perhaps a word of warning is not out of place to the man in charge of the boiler. If he does not thoroughly understand the use of a caulking tool, let him get some lessons from someone who does before he starts in, or better still, get a tradesman to do the job. An unskilled hand with a caulking tool can do a lot of harm in a very short time, and start more leaks than he can stop.

External Corrosion

Here is one of the most prolific causes of the depreciation in boilers, and one that is almost entirely due to sheer neglect. It is common enough to see well built and expensive boilers in a state of practical decrepitude after a very short life. It seems strange that this should be so after all that has been written and spoken and sworn on this subject, but that there is still need of preaching was proved to the writer only a few days ago, when he saw a boiler practically corroded away in one spot while the rest was good.

Now this form of corrosion is one to which every type of boiler, marine and stationary, is liable. However, the danger of corrosion is well understood aboard ship and conditions that lead to it are actively combated. It should be the same on shore, but in too many cases is not.

To consider first our old friend, the return tube, horizontal boiler, and the

particular variety of front known as the overhanging front. This is where the smoke box overhangs the brick setting, the breeching to the chimney being set directly on top, and the chimney itself often leading directly overhead. Here we have an ideal spot for corrosion to take place, especially where the boiler is shut down more or less frequently for a few days, or perhaps a season. Take cheese factories, canning factories, sawmills, etc., which are seasonal occupations. The soot and dust is allowed to accumulate round the front head, snow and rain filtering down the chimney, keeping it nice and moist. Perhaps when the boiler is working the hand hole or manhole is leaking also. The process of oxidization goes on merrily, and although perhaps a brush is employed occasionally on the tube plate and smoke box, it only removes the surface dirt. The layers of rust build up hard and solid looking till gradually the rivet heads are almost covered. Then some one comes along who recognizes the symptoms, and taking a hammer, proceeds to chip around the flange. If the owner of the boiler happens to be present he is astonished to see his property disintegrating before his eyes. When the chipping process is finished he will see what was originally perhaps a ⅜ in. or 7-16 in. plate has shrunk to a knife edge, and he is confronted with a nice repair bill. The dog that holds the hand hole in place, on being removed, will often disclose two badly corroded spots where it has rested on the head. The plate itself round the edges of the hand hole is very susceptible to the effects of continued leakage, rapidly becoming thin to the danger point. Around the back head seam is another favorite place for corrosion, due to leakage from the hand hole, or to wet soot lying in the combustion chamber, while the blow-down pipe itself and the pad on the boiler shell is often allowed to become badly corroded.

Right here let a word be said against the practice of building a brick pier around the blow-off pipe to protect it. This is bad in two ways. It is a trap for holding moisture, and encouraging rapid oxidization, and carried to lengths as it sometimes is, forms a breakwater against which the products of combustion impinge and are deflected to each side of the setting. This results in a certain amount of heating surface being lost. Whenever the boiler is washed out some water runs down the shell of the boiler and soaks into the space between bricks and pipe, and if the brick is close to the shell the water lies in between brick and shell.

The only protection a blow-off pipe needs is to be kept clear, and full of water. A paper bag can be filled with water and the water boiled over the gas flame without hurting the bag. A good circulating arrangement on the blow-down pipe is the best protection, but failing that, a short blow once or twice a day will ensure the pipe being clear.

Another place to look for corrosion is at the back head where the back arch rests against the boiler. Here again water is allowed to seep through from above to the ultimate destruction of the plate. As mentioned before, any place where leakage is taking place is a breeding place for corrosion.

Other types of boilers have their more vulnerable spots. In the Babcock and Wilcox type the short nipples connecting the back headers to the mud drums, and the mud drums themselves require careful examination. Very often these drums are close to the ground, and the space between the drum and back headers very small. If soot and dirt are allowed to accumulate in the back pass corrosion is almost certain. When blowing the tubes of Babcock and Wilcox boilers there is usually some leakage on the floor, and some of the water will find its way into the back pass. When the boiler is down for cleaning there is always considerable water splashing about, and if the space between mud drum and back headers has not been well brushed down before washing commences the soot soaks up the water and forms a wet plaster all round.

In vertical fire box boilers the bottom of the fire box under the grate bars is the place to find corrosion, especially under the ring that holds the grates. The ton tube plate also requires careful examination, especially in boilers working in the open where rain and snow can descend the stack. The plate, at the edges of hand holes is also to be watched for corrosion due to leakage. In Scotch marine boilers used for stationary purposes, the lower half of furnace tubes, circumferential seam below the furnaces, combustion chamber bottoms; in locomotive types the fire box below the grates and the smoke box end are the likely places.

Prevention of External Corrosion

The prevention of external corrosion is a question of keeping things clean. A boiler where tube plates and heating surfaces are kept brushed off and the metal visible has no chance to corrode. Clean ashpits in fire-box boilers, clean combustion chambers in bricked-in boilers, scrupulous cleanliness in every part is a sure preventive of this evil. The use of our old friend, white or red lead mixed with coal oil, is of benefit on furnace tubes, below the fire bars, on head flanges of horizontal return tube boilers, in the smoke box of loco type boilers, and any surface liable to corrosion that is not a heating surface.

Do not allow wet soot or ashes to lie against any part of the boiler. Wet ashes are the most violent corrosive agent that can be found. Don't close the boiler up if you have any doubts about manhole or hand-hole gaskets. Furthermore, I would say to chief engineers: "Don't take anybody's word about your boilers. Put on a boiler suit and see for yourself."

The little drop of water leaking from a gasket three or four feet above the shell of a boiler, two, three, or four drops a minute, wears its way through the covering to the shell, and although it apparently evaporates as soon as it strikes the hot metal, it is getting in its work just the same. If you can't stop it, put a piece of galvanized iron under it and lead it away. If you have any pipes in your plant and the asbestos covering is damp, tear it off till you find the cause and leave it off till remedied. Damp asbestos lying in an iron pipe, spells ultimate ruin.

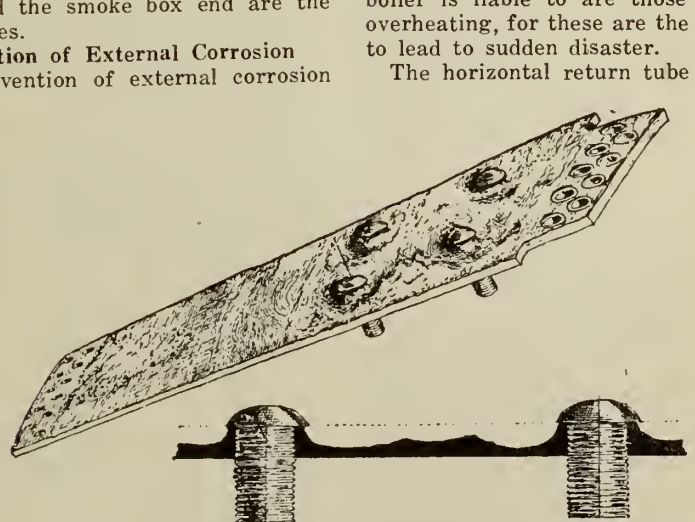
Corrosion is a mean, sneaking enemy that works without rest. It is busy when every other thing in the plant is stopped. It loves the dark. Don't give it a chance. Be as vigilant to detect it as it is to avoid your eye. Corrosion resembles a cancer to some extent, inasmuch as to stop it the affected part must be thoroughly cleansed of growth, and if left too long the part as well as the growth will have to go.

Troubles Due to Overheating

The most serious troubles that a boiler is liable to are those caused by overheating, for these are the ones liable to lead to sudden disaster.

The horizontal return tube boiler, being the one most largely used, will be considered first.

One of the most frequent effects of local overheating is found in the fire-cracks that develop on the plates where they are lapped to form the circumferential seams. While this trouble usually develops on the seam over the bridge wall it is also found both on the front and back seams.



MORE EXAMPLES OF CORROSION.

This is due partly to the way the setting is put in and partly to incrustation on the shell internally. A boiler with a ⅜ in. shell is ¾ in. thick at the lap, and one with a 7-16 in. shell is ⅞ in. thick at the lap. It follows the conductivity is just one half at these joints of the rest of the shell. Therefore, any accumulations of scale at these points are much worse in their effect than the same thickness of scale on a single thickness of plate. This effect is often aggravated by the form of the bridge wall, which directs a hot flame right on to the seam, causing intense local heat. The front seam is less liable to firecracks as if the setting is correctly made it will be out of the influence of the fire entirely. However, it is not so made in many cases, and not only is the seam left exposed to the flame, but a space is left between the fire arch and the boiler shell through which the draught sucks the flame, often burning the hand hole or manhole dogs.

The bridge wall should be made with a gradual slope from the back edge of the firebars, so as to allow the gases to pass over in a fairly straight sweep. With a straight bridge wall the flame and gas are thrown directly upwards, and if the bridge wall coincides with the seam trouble ensues.

Firecracks on the back head seam are nearly always due to scale accumulation, the back head flange being an awkward place to reach when cleaning the boiler. These firecracks usually start at the outside edge of the plate and run towards the rivet hole. They are not serious unless they show signs of starting from the inside edge of the rivet hole. If they do this they should be immediately plugged with a ⅛ in. or 3-16 in. plug and carefully watched. If, on the first sign of firecracks developing, careful attention be paid to the state of the boiler internally and the brickwork externally, their further spread may be checked. As a matter of fact, there are hundreds of boilers that are working with firecracks that first showed up years ago, and are no further advanced than when first apparent. However, firecracks are not to be dismissed with scorn but should be carefully watched at every examination of the boiler to ascertain their progress.

Another trouble due to burning is caused by carelessly-built settings. The back arch of a horizontal return tube boiler should be built immediately above the top row of tubes. Sometimes it is built so high above the tubes that the heads of the rivets securing the stays are exposed to the flame. Further, the plate is likely to be overheated as the water level is often below the height of the arch. This point is often neglected when the arch is being built, and is sure to give trouble sooner or later. The least that happens is the burning off of the rivet heads. Where there is a hand hole in the back head the dog and bolt head that holds the door is almost always burnt off when the time comes to open it up. This is not so serious as it seems, for as long as the boiler is under pressure the door is held up to its place automatically. It is hard to prevent this burning, but sometimes covering the dog and bolt with asbestos will help a lot.

The source of greatest danger is overheating of the shell plate directly over the fire. This is invariably caused by a deposit of scale, or grease that keeps the water from contact with the plate. Transmission of heat is greatly retarded, and instead of the heat of the furnace being absorbed by the water, it is absorbed by the plate, which becomes overheated locally. The result is a bulging of the plate to a greater or less extent, according to the area affected, and the degree of heat attained. If the deformation is sufficient to draw the plate down to extreme thinness a rupture will occur, and a disastrous explosion follow.

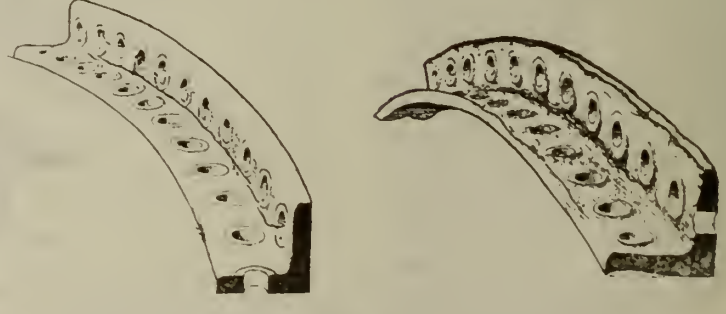
In the firebox boiler of the vertical type, there is danger of the narrow water space between firebox and shell becoming made up with scale and the plate overheating. In boilers with circular furnace tubes there is danger of collapse through overheating, and in the Scotch marine type the combustion chamber crown is a vulnerable spot.

The Effect of Oil

Many men in charge of boilers seem to think that the effect of oil on heating surfaces is exaggerated. The effect of oil on heat transmission cannot well be exaggerated. The following example should serve to convey to the mind of any doubter just what oil can do. These experiments were two of a number carried out by a Professor Durston in England:

A horizontal tube 2½ inches diameter. 10 inches in length, and with walls .135 inch thick, perfectly clean, was tested with an exactly similar tube which had been smeared with oil from a paint brush. The result showed a decrease in heating efficiency of from 8 to 15 per cent., the average of a number of tests being 11 per cent.

The second test was with a 10 inch circular disk 10 in. diameter, 3 in. deep, and ¼ in. thick. The furnace temperature was 1,500 deg. Fahr. With clean surfaces the temperature of the water side of the plate was 212 deg., and the fire side 240 deg. With a coating of grease on the water side of the plate, 1-32 in. thick, the corresponding temperatures were 212 deg. and 330 deg. That is an increase in the temperature of the plate of 31 per cent. These figures should convince the most sceptical.



GROOVING.

Prevention and Repair

If the cause of overheated plates is scale and oil, obviously the way to prevent them is to keep the surfaces clean.

As far as oil is concerned this can be done by passing all exhaust steam used for boiler feeding purposes through efficient oil separators. Give the oil separators a chance, likewise the oil bell, by using the minimum amount of cylinder oil to run the job. Cylinder oil was not meant to be used as a chorus girl uses powder. If your pumps are lifting water from a hot well, put the suction well down so that oil can float on the top if there is any coming in. Watch the gauge glass if you have an open heater, for globules of oil on the water, and watch the boiler gauge glasses for the same thing. Eternal vigilance is the price of safety.

As regards scale formation, this will depend on the quality of the feed water and the amount evaporated.

As a rule the judicious use of ordinary washing soda will solve most scale troubles. Of course, in districts where the water is highly charged with sediments that solidify easily, special care is needed. Each case must be treated on its merits. The following prescriptions are excellent in a general way, being safe and effective, and above all, inexpensive.

When Carbonate of Lime is Present

For each grain per gallon of water found in the boiler use 1½ ounces of pure caustic soda per 1,000 gallons of water evaporated.

When Sulphate of Lime Alone is Present

For every grain of sulphate found in the water, 1¾ ounces of pure carbonate or soda (soda ash) are required per 1,000 gallons evaporated.

When Both Carbonate of Lime and Sulphate are Present

Caustic soda will precipitate both these salts in the following proportion: If water contains 6 grains of carbonate per gallon it would require 6 by 1½ equals 9 ounces of caustic soda per 1.000 gallons, and this would also eliminate 8.16 grains of sulphate. This is water containing 14.16 grains of solid matter per gallon, of which 6 were carbonate and 8.16 sulphate, could be treated by adding sufficient caustic soda to remove the carbonate.

Take a boiler evaporating 1,000 gallons of water per day. The water contains 26.32 grains of solid matter per gallon. Of this 6 grains are carbonate, 16.32

Fuel-Burning Equipment of Modern Power Stations

The Following Article Treats of One Form of Stoker, the Inclined Multiple Retort, and Gives Some Interesting Data Relative to Large Installations Which Have Been Completed in the United States

By JOSEPH G. WORKER

Manager Stoker Section Westinghouse Electric & Mfg. Co.

WAR necessities brought about, to a certain degree, "conventional" steam power plants. The activities of the different Government administrations, however, have exacted requirements, in detail, conducive to the highest economic operating results. Production, on the one hand, has made the different public service corporations face the necessity of increased power facilities, and the requirements of fuel conservation, on the other hand, have demanded a careful study of detail problems, not only in the selection of equipment, but in providing means for its economical operation. The co-operative activity of the power plant management, with all these problems, cannot be better exemplified than in the character of the steam equipment designed for recent installations of new steam plants.

A study of the fuel burning equipment of the most modern plants will show that every consideration is being given to those details which provide for a balancing of the economic results that come from a careful selection of equipment, good supervision and correct operation. It will be found that elaborate means are being provided so that the boiler room organization can do things easily. It is no longer necessary for firemen to climb ladders and crawl over the boiler tops to change the position of dampers, although such methods are still common in many old plants. Mechanisms are being placed at the hands of the operators so that it is not necessary for them to go to inconvenient places in order to control operating conditions.

The most generally used fuel-burning equipment for large boilers in the modern stations, is the "inclined multiple retort" underfeed stoker, designed for large boiler units, ranging from 1,200 to 1,500 h.p. A number of boilers containing 12,600 square feet of heating surface have been used, and are furnishing steam for 7,000 to 8,000 kw. in the prime mover. It is not at all improbable that this unit will be further developed to furnish steam for at least 10,000 kw., in the prime mover for continuous operation. These units are set singly, with large alleyways between each setting, so that the boiler and fuel-burning equipment are accessible on all sides. The stokers are designed for a flexible operation of 50 to 300 per cent. rating. Clinker grinders are used in a number of cases for discharging the ash and refuse automatically.

FIG. 2—INTERIOR VIEW OF BOSTON EDISON FURNACE.

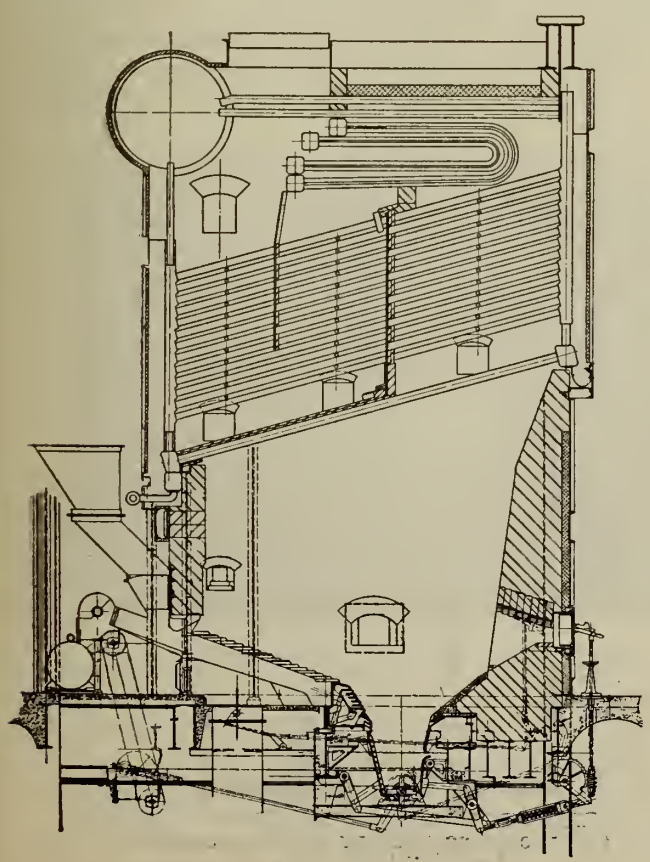

FIG. 1—CROSO DRUM BOILER SETTING USED BY THE BOSTON EDISON CO.

The following brief description of the fuel-burning equipment recently installed in a number of modern power stations covers a wide range in the character of load and fuel used. Some of these plants are completely new stations, while others are extensions to old stations, and still others are old stations in which inadequate fuel-burning equipment has been replaced by more modern equipment.

Edison Electric Illuminating Company of Boston

This company has replaced the old fuel burning equipment under eight 512 h.p. boilers with inclined underfeed stokers. One of these stokers was equipped with a clinker grinder, the idea being to try this out under regular operating conditions and with the fuel available, this being a part of a study for the new extension to the station. Although the stoker was of small size (five retorts), the clinker grinder operated satisfactorily, and it was decided to use this design in connection with the equipment for the new extension, consisting of four cross-drum boilers, 42 sections wide, 14 tubes high, and 18 ft. long, rated at 1,232 h.p., at 300 lb. gauge pressure, equipped with a superheater designed to give 150 degrees superheat.

These stokers, as shown in Fig. 1, are of the underfeed type, having 13 retorts installed under the back end of the boiler, under the mud drums, and equipped with rotary clinker grinders, Fig. 2, for removing the ash and clinker continuously. The stoker drives, Fig. 3, are divided with not over four retorts to a

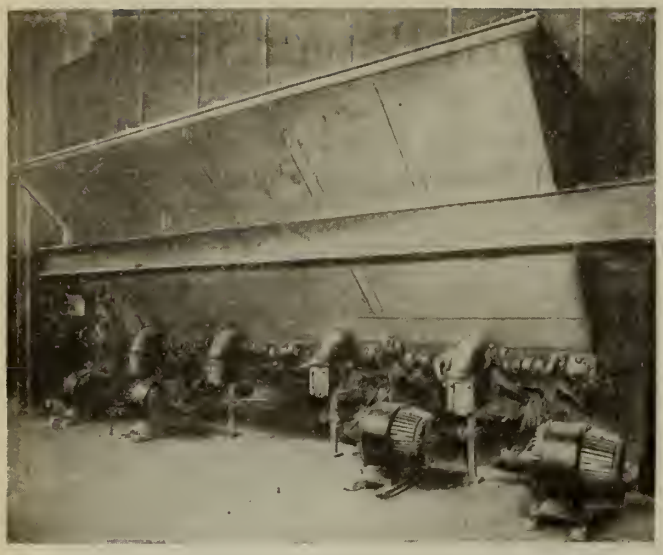

FIG. 4—REAR VIEW OF BOSTON EDISON BOILERS SHOWING INDICATING INSTRUMENTS, VALVE PEDESTALS, ETC.

motor; also the wind boxes and dampers are so arranged that they can be controlled on the same basis, this provision being made so as to give a complete control of coal and air across the entire furnace width.

The coal usually used is New River, of approximately the following analysis:

Fixed carbon	73.50
Volatile	20.75
Ash	5.75
Moisture	3.25
Sulphur	1.05
B. t. u.	14700

The average per cent. of combustible in the ash and refuse is not to exceed 15 per cent. The stoker equipment, when supplied with the above fuel. is designed to develop 30 per cent. of normal rating of the boilers for periods of short duration.

The Boston Edison engineers worked out a design in which doors are placed on the bridge wall, and all controlling mechanism placed at the end opposite the stokers, Fig. 4, so that when the operator views the furnace fires through the bridge wall doors he will have at hand the controlling mechanism.

Buffalo General Electric Co.

The fuel-burning equipment for a recent extension of this company's boiler plant consists of 24-retort underfeed stokers, applied to 1,140 h.p. cross-drum boilers, Fig. 3. The stoker equipment is designed for burning high volatile Pittsburgh coal, of about 13,500 b.t.u. as fired, 10 per cent. ash, 3 per cent. moisture, and two per cent. sulphur. Air-admitting dump grates are furnished with the stoker equipment, these being power-operated. To eliminate, as much as possible, the formation of clinkers, air boxes were designed for installation in the side wall.

The combined efficiency for the plant's operating conditions will range from 75 per cent. at 200 per cent. of boiler rating, to 65 per cent. at 500 per cent. of boiler rating. The coal burning equipment is designed for continuous capacity of 480 per cent. of boiler rating, and 600 per cent. for short durations. In comparison, this boiler has 24 retorts installed under an 1,140 h.p. boiler, while at the Delray station of the Detroit Edison Co., there are 26 retorts installed under a 2,365 h.p. boiler.

Union Gas & Electric Co., Cincinnati

The new $8,000,000 plant of this company contemplated the installation of eight cross-drum type boilers containing approximately 12,625 sq. ft. of water heating surface, with superheaters to produce 250 degrees of superheat. Each boiler was made up of 42 sections each, 13 tubes high and 20 feet long, the furnace width being 24 feet inside the setting walls. Each boiler is equipped with economizers over the boiler and each boiler, with economizer, is designed for evaporating 100,000 pounds of water per hour continuously from 100 degrees to steam at 250 pounds pressure, and superheated 250 degrees, Fig. 6. The entire equipment is capable of evaporating 120,000 lbs. of water under the same conditions for short periods. The fuel burning equipment is designed for burning West Virginia coal, from the Kanawa district, containing approximately 12,500 b.t.u. per pound as fired.

The stoker equipment is of the underfeed type, each stoker containing 14 retorts placed under the rear of the boiler under the mud drum. The stokers consist of double dumping grates with arrangements for admitting air to them. The fuel burning equipment is designed for combined efficiency ranging from 75 per cent., with a boiler capacity of 35,000 pounds of water, to 65 per cent., with a capacity of 100,000 pounds of water. Each stoker is driven independently by direct current motors, connected by Morse silent chain drives to the line shaft of the stokers. Instrument boards are installed to indicate to the operators the exact furnace conditions.

American Gas & Electric Company, Windsor, W. Va.

The $10,000,000 plant of this company,

FIG. 3—FRONT VIEW OF STOKERS

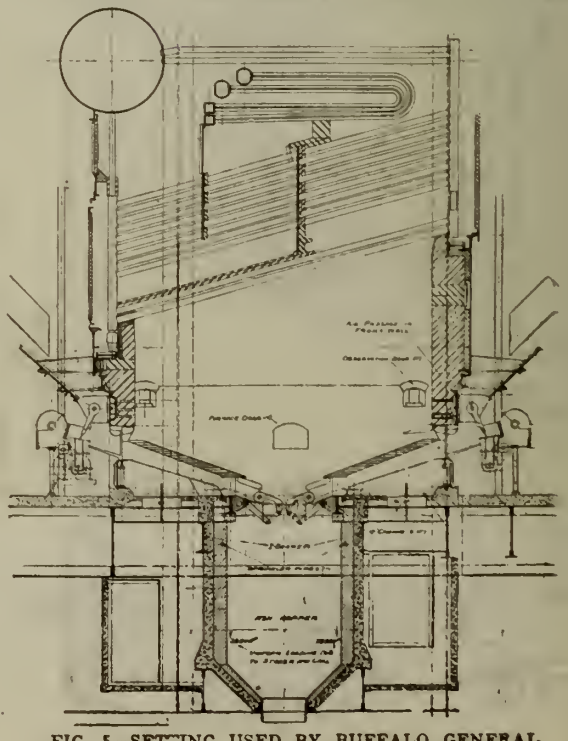

FIG. 5—SETTING USED BY BUFFALO GENERAL ELECTRIC COMPANY.

located in the coal fields of Pittsburgh, is one of our largest power plant developments of recent years. The present boiler-room equipment, Fig. 7, either installed or provided for, consists of 14 boilers with underfeed stokers similar to the equipment mentioned for the Union Gas & Electric Co. The setting of the stokers is shown in Fig. 8, and the instrument boards, as shown in Fig. 9, are placed between each boiler in the aisles.

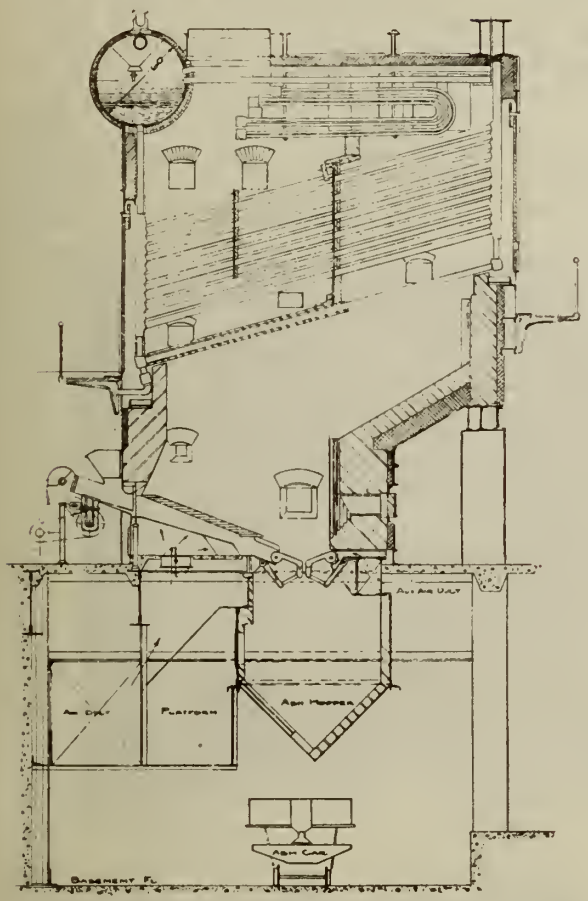

FIG. 6—STOKER AND BOILER ARRANGEMENT AT THE PLANT OF THE UNION GAS AND ELECTRIC CO., CINCINNATI.

FIG. 7—MOTOR AND CONTROL MECHANISM OF THE STOKER.

Detroit Edison Co.

The front view of the boiler and stoker equipment installed at the Delray plant of the Detroit Edison Co., is shown in Fig. 10. This consists of 2,365 h.p. boilers equipped with 26-retort underfeed stokers, with clinker grinders. The Detroit Edison Co. engineers have done considerable work in the development of these clinker grinders. Difficulty was at first experienced on account of the fuel bed breaking, where the fuel left the underfeed part of the stoker, and going into the ash well. It will be noted from Fig. 10 that the grate surface has been curved, this being done in order to eliminate the breaks in the fire. This equipment is run ordinarily at about 150 per cent. of boiler rating, but higher capacities can be obtained when necesary. The coal used contains about 13,200 b.t.u. as fired, and 10 per cent, ash. Under the above operating conditions, the combustible in the ash runs from 14 to 18 per cent.

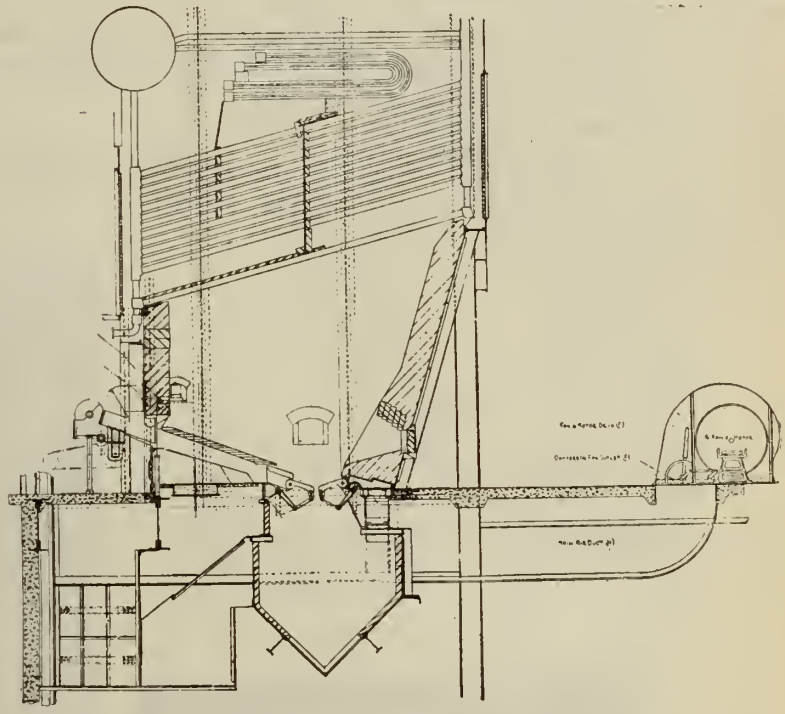

FIG. 8 STOKER AND BOILER EQUIPMENT AT THE AMERICAN GAS ELECTRIC CO. PLANT.

FIG. 9—INSTRUMENT BOARD USED IN CONNECTION WITH THE STOKERS AND BOILERS SHOWN IN FIGS. 7 AND 8.

The instrument board used for indicat-

ing to the operators the condition of the furnace is shown in Fig. 11. It will be noted that everything possible is provided to facilitate ease in handling the controlling equipment.

West Penn Power Co., Pittsburgh, Pa.

The new plant of the West Penn Power Co., on the Allegheny River, above Pittsburgh, contemplates some decidedly novel features in the boiler and stokeroom equipment. The initial installation is designed for six boilers of the cross-drum vertical-header type, 42 sections wide, 16 tubes high, 20 ft. long, set with the front header 16 ft. above the floor, each boiler being rated at 1,529 h. p., and equipped with superheaters designed to give 200 degrees superheat. Underfeed stokers are to be installed at the front and rear ends of the boilers, Fig. 12, 14 retorts under the mud drum, and 14 retorts under the front of the boiler. The operating conditions are to be a maximum of 300 pounds gauge pressure, 200 degrees superheat.

The boilers will be set in two rows, with aisles about 15 ft. between, thus giving plenty of room around each boiler for proper operating facilities. The stoker drives are so divided that there will be 7 or 14 retorts driven by one prime mover, and the wind box dampers are arranged to control separately the air for units of 3 or 4 retorts. The stokers are to be equipped with clinker grinders for continuously removing the ash and clinker. Pittsburgh coals will be used, with approximately the following analysis:

Analysis:

	Coal "A"	Coal "B"	Coal "C"
Fixed carbon	57.38	49.96	56.55
Volatile	34.81	32.84	32.80
Ash	7.81	13.26	10.10
Moisture	5.52	0.94	0.55
Sulphur	1.50	1.20	0.79
B. t. u. (as fired)	13500	11748	12713

The boiler equipment is designed so that the flue gas temperature will range from 500 degrees at 150 per cent. rating to 700 degrees at 300 per cent. ratin, the combined efficiency ranging from 75 per cent. at 150 per cent. rating, to 65 per cent. at 350 per cent. rating. Each stoker, when burning fuel as mentioned above, is designed to develop 350 per cent. of boiler rating continuous with the clinker grinder in operation, and 400 per cent. of boiler rating, for peaks of short duration. Under these operating conditions, the combustible in ash is not to exceed 14 per cent., and the ash is to be discharged into water-sealed ash pits.

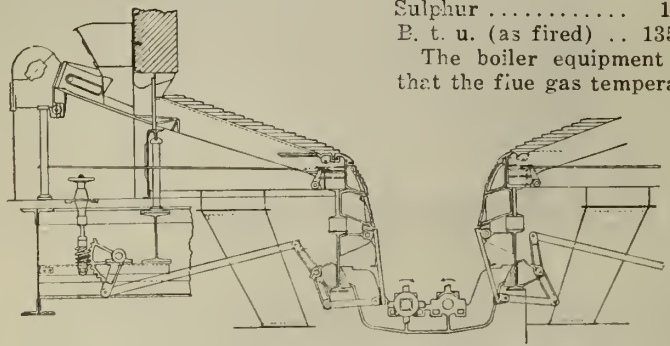

FIG. 10—SECTIONAL VIEW OF STOKERS AT THE DELRAY STATION, DETROIT EDISON CO.

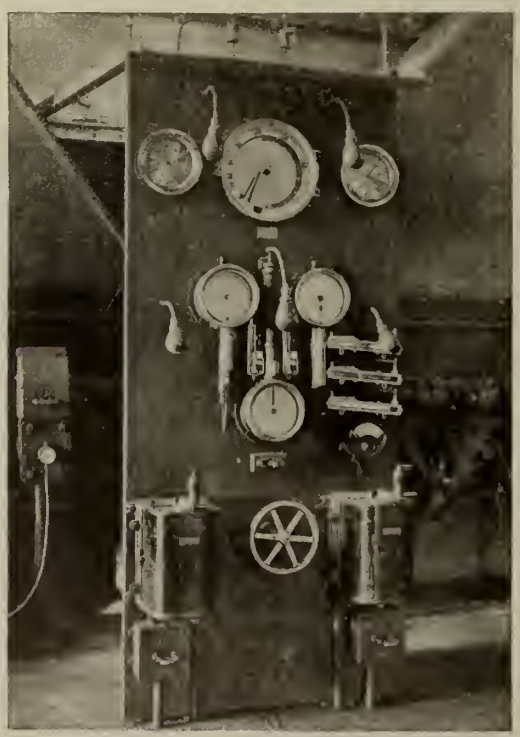

FIG. 11—INSTRUMENT BOARD AT THE DELRAY STATION.

Minneapolis General Electric Co.

The engineers for H. M. Byllesby Co. have been very active in redesigning the fuel burning equipment of plants under their management. For example, at the Minneapolis General Electric Company's plant, Fig. 13, there were installed 12 underfeed stokers, under twelve 600 h.p. boilers. A recent extension to this plant contemplates the installation of five 14-retort underfeed stokers under five 1,300 h. p. boilers. On account of the coal conditions prevailing at this plant, it was necessary to design equipments for two grades of coal of the following approximate analyses:

	"Coal" A	Coal "B"
Fixed carbon	56.48	43.49
Volatile	30.81	32.59
Ash	11.03	20.40
Moisture	7.00	10.00
Sulphur	1.70	3.48
B. t. u.	13400 dry	11200 dry

Under the above conditions, the operating performance of fuel "A" ranged from 1,800 to 3,000 h.p. continuous, and 4,500 h.p. for short durations. With the poorer grade of coal, the maximum capacity was reduced to 3,000 h.p. for short durations.

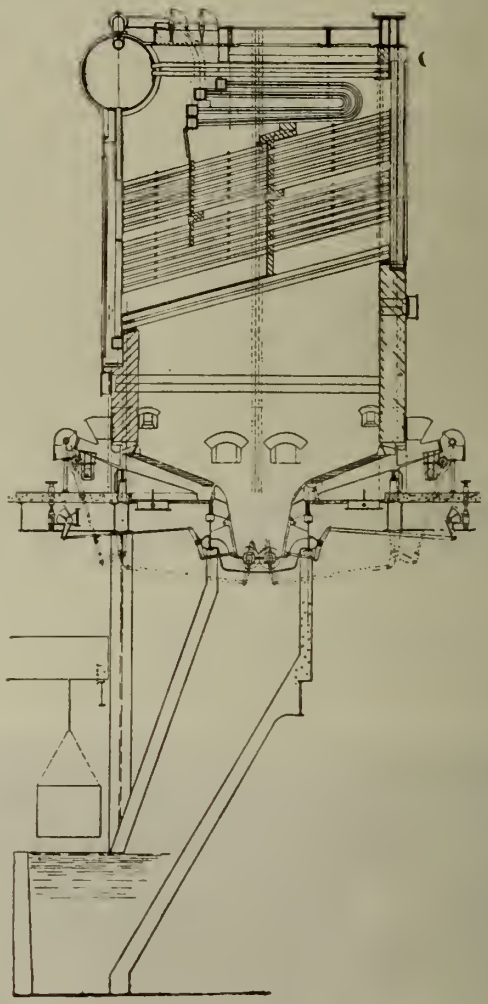

FIG. 12—SECTIONAL VIEW OF STOKER AND BOILER APPLICATION FOR THE WEST PENN POWER COMPANY'S NEW STATION, PITTSBURGH, PA.

Union Electric Light & Power Co., St. Louis

In the past year or so, the boiler plant

of the above company has been entirely revamped, and a change made in the type of fuel burning equipment formerly used. Careful study was made in regard to the installation of stokers, and it was finally decided to install underfeed stokers for use with good Illinois coal, of the following analysis:

Fixed carbon	48.9
Volatile	27.3
Ash	14.9
Moisture	8.9
B. t. u. (as fired)	11112

The main problem at the start was that of designing the equipment to eliminate, as much as possible, trouble due to clinker formation on the side walls. After the equipment was in operation, and when using the coal that was originally contemplated, very little difficulty was encountered with clinkers. Performance results are shown in Fig. 14, when a grade of coal with the following analysis is used:

Fixed carbon	41.0
Volatile	29.0
Moisture	9.0
Ash	21.7
B. t. u. (dry)	12000

Considerably more attention was required to keep the fires uniform and cleaned properly in order to decrease clinker trouble to a minimum.

FIG. 13—STOKER EQUIPMENT OF THE MINNEAPOLIS GENERAL ELECTRIC CO.

Denver Gas & Electric Co.

Recent developments in the West have brought about the installation of underfeed stokers for burning coals found in the Denver markets. The above company's new extension contemplates the installation of four 750 h.p. boilers and four 9-retort underfeed stokers. The application setting worked out as shown in Fig. 15 was made to give sufficient combustion space for any high volatile coals that were liable to be used at this plant, including lignite. The fuel burning equipment has been designed for the following coals:

Fixed carbon	39.00
Volatile	35.85
Moisture	19.70
Ash	5.37
Sulphur	0.42
B. t. u. (dry)	12000

When using the above fuel, the operating performance ranges from 140 per cent. boiler rating to 200 per cent. boiler rating for short duration, with approximately 70 per cent. combined boiler and furnace efficiency.

Does every man in your plant read POWER HOUSE? Then you owe it to him to direct his attention to our paper. 'Twill help him as it has helped you. Remarkable offer—$1.00 per year now. Subscribe for several years in advance and secure this rate.

Operating the Babcock Chain Grate Stoker

The Author in the Following Article Gives the Result of Operating Experience and Gives Valuable Hints for the Operation of Chain Grate Stokers in General

By S. BALMFIRTH

THE writer having had charge of B. & W. boilers and chain grate stokers for some five years or so, has during that time engaged quite a number of engineers and firemen, but has not, during the entire period, found one man who knew anything of stokers, or who had handled them in any way. Consequently, the writer has been obliged to instruct every one of them. Experience teaches, but the cost of the course is often high.

It generally costs anything from $50 to $100 to break a new man on boiler firing, if the engineer on the watch is at all busy. So to help cut down the H. C. of L. (which being interpreted, is the high cost of learning,) the writer offers the following suggestions, the value of which has been proved by experience, the hope that they will prove of benefit to some fellow craftsman.

The Babcock chain grate stoker is a splendidly made machine for its purpose, but like all other machines requiring intelligent care, otherwise it is bound to give trouble.

A study of the illustrations will show that it is made up of three main parts: The grate proper, the feed mechanism, and the driving gear. The grate is made up of two kinds of links, the common, and the driving links. These last mesh with the sprockets in front and receive their motion from them.

At the rear half of the grate will be noticed flat plates F F, placed in an oblique direction: these are shutters or vanes, to be used to increase or decrease the rate of combustion according as the load on the boiler is heavy or light. When the grate is running it is supported by rollers, A A, these giving the grate a slight rocking motion, helping to break up any coke that may form, and also shaking down ashes.

During operation of the stoker the grate should be tightened sufficiently to be flat on top, and without any sag.

As will be seen in the illustration, the feed arrangement consists of door B, together with gearing to raise and lower the same. The door is made up of cast iron top, bottom and sides and is filled with firebrick.

One source of trouble with chain grate stokers is the feed door. Some coals will coke and burn close up to the door, and so get it too hot. But one of the most frequent causes of trouble, is the lack of knowledge on the part of the fireman on how to handle the boiler on light load or on how to bank the fire.

The driving gear consists of a train of spur and worm gears. These are driven by a roller chain from a sprocket on the countershaft to a sprocket on the driving shaft of the transmission gears.

There are four changes of speed obtainable through the transmission device, by means of a rack and pinion. Thus it is possible to change the speed of one stoker without altering the speed of another though both are being driven from the same countershaft.

The motion is transmitted to a worm, driving a worm wheel on the front sprocket shaft of the stoker. One point to be remembered is that the clutch nut should only be tight enough to drive grate. It is best to tighten this nut with the driving chain running, then it is only necessary to keep on tightening until the clutch picks up its load.

It should be possible to hold the grate with the ratchet wrench supplied with it, with the clutch in. In fact this clutch is a safety device, if it is not made inoperative through being set up too tightly.

One of the main features of the Babcock stoker is the ignition arch. This is of course of firebrick and is about four feet long, extending back, directly behind the feed door.

Until this arch is thoroughly heated, the stoker will make smoke, and also it is not possible to operate this stoker if for any reason this arch cools, which is quite possible, as will be shown later.

Whether the installation is a new one, or the boiler is being put into commission after cleaning, it is always best to work the stoker entirely round by hand. This may save considerable trouble later. To illustrate, some little time ago, the writer had a stoker overhauled, during which process it was found necessary to renew a good many links both common and driving.

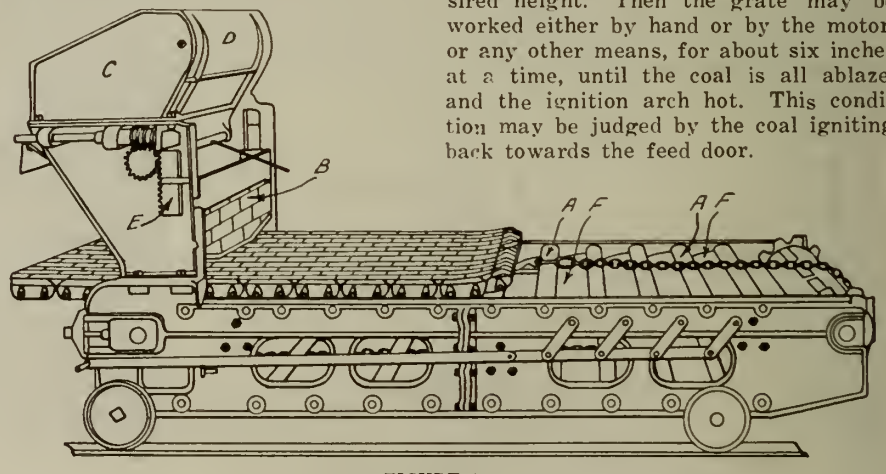

FIGURE 1

As there is always a right and a wrong way of doing things, and as, further, too many cooks are apt to spoil the dinner, it so happened that some of the driving links were placed in wrong. The stoker had been pulled out from under the boiler, for overhauling, and as the time was short, it was pushed back into place, and the fire lighted. By the time the fire had been worked to the back, there was about 20 lbs. pressure, and then it was discovered that the grate would not run. It had gone quite freely up to a certain spot then it stuck. So there was nothing for it but to let the fire out and draw out the stoker again. It was found that the driving links in two places, of course, in the middle of the width of the grate, had been placed back to back, instead of face to face.

Having turned the grate round (this is done of course with the clutch nut loose.) it may be covered with coal about three or four feet in, but not further. If ashes are available for covering the rear of the grate all the better. The feed door must be lifted out of the way, for at best there is only about eight inches of an opening at the front. The fire is then lighted in the usual way, keeping it well forward, the idea being to get the ignition arch as hot as possible.

When the fire is well under way, the front of the hopper may be closed and the hopper filled. Open the coal shutter and lower the feed apron to the desired height. Then the grate may be worked either by hand or by the motor, or any other means, for about six inches at a time, until the coal is all ablaze, and the ignition arch hot. This condition may be judged by the coal igniting back towards the feed door.

One point to be observed in starting a stoker is, that the draft should be checked by keeping the damper partly closed until the fire is well alight back to the feed door.

Possibly some reader is wondering why the grates should only be covered with coal for three or four feet, and the back of the grate with ashes. If all the grate be covered with coal it will not all ignite whilst the fire is gathering strength, and as soon as the grate begins to move, much of the coal will be dumped over the back, so it is better to

cover the back of the grate with ashes.

The chain grate stoker is adapted to burning bituminous slack, under natural draft, without smoke. In fact the writer always goes hunting for trouble if any smoke appears at the stack, and generally finds it. The appearance of smoke generally indicates that the fire is carried too far back, that is, when the boiler has been in operation for any time. Smoke is always formed at starting up, but when the ignition arch is properly heated there is practically no smoke formed whatever. There is another condition, however, which will tend to the formation of smoke, and that is, insufficient draft, but generally speaking. smoke is the result of too much fire. The carrying of the fire too far may be due to the fire bed being too thick, the grate speed too high, or the draft too low, or a combination of all three; but, whatever the cause, the result is always the same, burned-out ash plates. These plates can be seen in the illustration.

No set rules can be given for the proper thickness of fire, or the speed of the grate. However, given a draft, at the breeching of .6 of an inch, and fairly fine slack, a fire of from 3½ in. to 5 in. thick will give good results. When the load on the boiler is light, the vanes shown at the back of the grates may be closed; this reduces the draft through the back end of the grates and prevents holes forming at the back of the fire.

The proper condition in which to have the fire is just to get the coal consumed by the time it reaches the noses of the ash plates. If it does not reach the ash plates, but is burned out before, cold air is drawn through the ashes, resulting in a loss of efficiency; if carried too far there is a great danger of burning out the plates.

One fireman that the writer had, had a trick of running the fire over the back, then dumping the fire into the pit, and leaving it there, with the result that one day there was a nice large hole in the dump door.

With some coals, especially coking coals, it is necessary to rake over the fire frequently through the middle sight door, otherwise there is a considerable loss by excess air being drawn through the fire. Some coals require more raking than others. The writer is quite aware that this procedure is not according to Hoyle, but sometimes it has made all the difference between having sufficient steam and not having it, on the writer's plant.

In the earlier part of this article it was mentioned that it was possible for the ignition arch to get cooled off. At first sight, the writer knows that this seems impossible, but it has happened quite frequently that the boiler fires have gone out, in, fact, one morning it happened twice within the space of two hours.

This trouble was caused by the coal changing from fine to almost nut coal, so that the feed was not deep enough for the nut coal; cold air passed through the coal bed and the fire ran away from the coal. This is one of the most annoying things that can happen.

About the quickest thing to do if the fire has not got far away from the feed apron, is: Close the feed shutter, run the apron right up, and opening the front of the hopper, pull the fire forward again.

In case the fire has got too far away, about the only thing to do is to feed wood in through the sight door, and push it forward under the arch again, always partly closing the damper, as, naturally, whilst this is in progress, steam is going down. This never happens except on a heavy load, when there is not an ounce of steam to spare.

To prevent this happening when the coal changes in texture, it is necessary to alter the thickness of the fire and the speed of the grate to suit the coal.

One thing to be avoided as a plague, is to get the fire so thick or the speed of the grate so high, or both, as to make it necessary to stop the grate. There is nothing worse for the grate, or that will shorten its life more than to stop it with a heavy fire on. What generally happens is that the corners of the links burn off and the links themselves get hot, and there is a great danger of the grate sticking fast. The writer has had all these things happen to him.

Lastly, the back of the grate must be watched to prevent the ash plates being thrown back by clinkers. With some coals it is almost a continuous process keeping the back of the grate clear. A coal that is high in ash and sulphur should not be used; about 2 per cent. sulphur being the safe limit. Two boilers are somewhat difficult to manage on light load, so one fireman tried carrying practically all the load on one boiler and banking the other, so he just nearly closed the damper and stopped the stoker. It worked beautifully, only next day the fireman relieving him had his own troubles. The coal in the hopper had all coked, and hopper sides were hot and coked more coal so it would hardly feed, and before the day was out the bricks dropped out of the door, because the fire had burned back up into the hopper, and in doing so, had also burned the door bottom in two. So that the following night it was necessary to put in a new door. This was done by taking off the hopper top, Nos. C and D, taking off the apron racks, E, and lifting out the remnants of the apron and putting in the new one. This takes about three hours from start to finish, and is not a pleasant task at best.

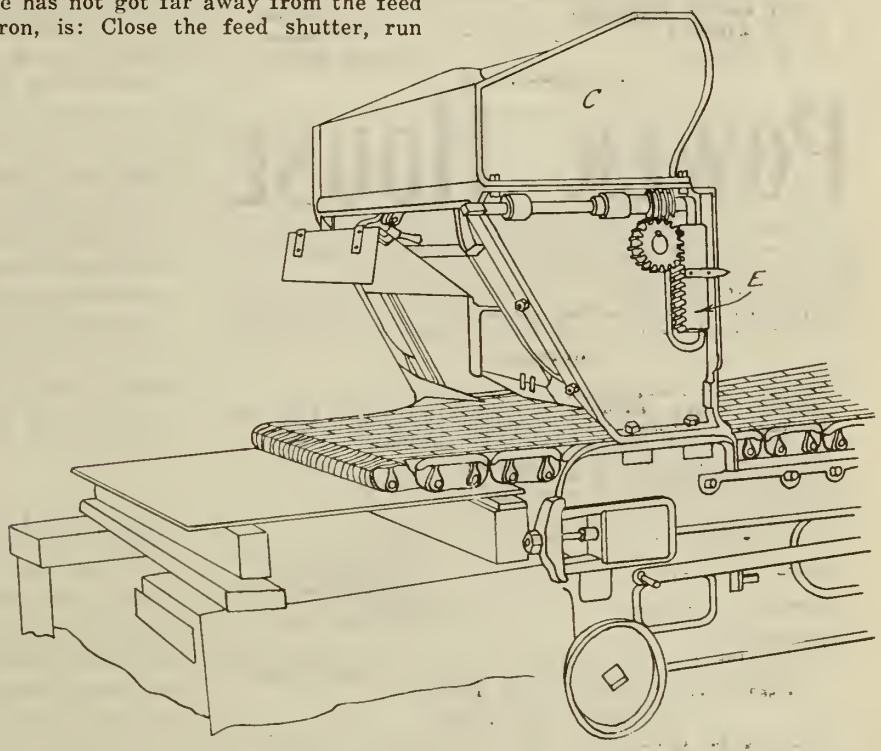

FIGURE 2.

To properly bank a chain grate stoker fire, the following is the method of procedure. Stop the grate until about half the fire is burned out. Then, with the door up to the top, run the grate at high speed. This will bring a thick bed of green coal under the ignition arch too fast for it to be burned. When it is judged that sufficient coal is on the grate to carry over the time needed, close the feed shutter, which is inside the hopper and is not shown in the illustration, and allow the coal below the shutter to be carried on the grate. When the last of the coal is from six to twelve inches away from the door, stop the stoker, lower the feed door to the bottom, nearly close the damper, leaving open just sufficiently to take away the smoke.

The fire will keep alight and will keep the arch hot for hours, without damage to the hopper or shutter or apron. When breaking up the fire again, instead of pushing it back, as under a hand-fired boiler, pull it forward.

Power Plant Efficiency

IT is interesting to note the growing importance attached to combustion and the boiler room in general, evidenced in the many articles which have appeared of late in the technical press. Power plant efficiency is of more than academic interest to both engineer and plant owner, and anything tending to the cheaper production of steam is eagerly welcomed.

With the progress which has taken place in the turbine little more can be hoped for in the more efficient utilization of steam in the generation of power and it is to the boiler room that efforts will have to be directed in the main for the securing of further economies.

This, after all, is to be expected, for the coal pile is the greatest source of trouble and expense, and the saving of a pound of coal by proper combustion practice is of more value than the securing of an equal economy in the prime mover at a greater capital expense.

It may be safely stated that the average boiler room is operated at much less than its possible efficiency even if no extra equipment is purchased and with proper attention to the various factors entering into the combustion of coal much can be done to decrease the cost of steam power or heating.

In securing proper combustion it is self-evident that the engineer must know how his coal is being burned and more attention will have to be paid to the equipping of the boiler room with instruments for the checking up of the various steps from the coal pile to the stop valve. The average boiler room makes but a poor showing when compared with the turbine or engine room with its meters and recording apparatus for every conceivable purpose.

Together with the control of combustion goes the proper handling of coal and ashes, and a little thought and the expenditure of a little money in this portion of the plant will not only make the fireman's lot easier but will show returns on the balance sheet.

Hitching Big Ben to the Central Station

AN interesting development in A.C. transmission has rather interesting possibilities for the future. An electrical clock has been developed, driven by a small synchronous motor which utilizes the frequency of an alternating current circuit for its functioning. The principle involved is very simple but in its carrying out very accurate control of the generator frequency will be necessary. This has been accomplished by the use of a similar clock mechanism together with a very accurate clock movement of the ordinary kind, although wound up by electrical means. When this device comes into general use it will render the accurate keeping of time a very simple matter, an accuracy of a few seconds a month being a comparatively simple achievement.

No doubt somebody will ask, "What are you going to do if power goes off?" This contingency will be taken care of by an auxiliary clockwork mechanism which will come into play when the power supply is interrupted and will cease functioning when it is restored.

Turbine Locomotives

THE one field in which the reciprocating engine has held its own is to be invaded at last by its deadly competitor, the turbine. A turbine driven locomotive has been designed in Europe which gives promise of at least being quite useful. The use of an impulse type, non-condensing turbine has been suggested which will be reversible and which must work economically at various speeds.

One suggestion is to the effect that a single steam turbine be placed in front of the boiler on a specially low frame with two axles. The axis of the turbine follows the direction of the rails, and drives through worm gearing, an auxiliary shaft lying in the direction of the wheel axles and supported on the front frame structure. At each end of this shaft is a crank from which the motion of the turbine is transmitted to the driving wheels by coupling rods. The axial thrust of this turbine is taken up by a special thrust bearing and the most suitable type of turbine to use in this case is a pressure turbine with a rotor for forward and one for reverse motion.

Well, This Sounds Like Real Easy Money

Written by One Who Had It Tossed at Him

LOOKING over CANADIAN MACHINERY a couple of weeks ago, I saw an article headed "Is There Such a Thing As Easy Money?" That is, in the nature of things, a highly controversial subject, and complicated by the fact that the ones who get their money in the easiest manner, think it is obtained only with difficulty.

Personally, the pursuit of the elusive dollar has always been fraught with hard labor and indifferent success. Only one occasion comes to my mind wherein I was the hunted, and the prettily engraved paper, the pursuer, Even at that, the manner of its coming was attended with so much mystery and anxiety of mind, that I doubt if it could be strictly labelled as "easy money."

The means by which I was, at that time, endeavoring to lay the foundations of a fortune, was by taking charge of the steam plant of a manufacturing concern. The salary was in inverse proportions to the duties. This particular plant had started in a modest way some years before, the motive power at the beginning consisting of a vertical firebox boiler, and a 15 h.p. horizontal engine. The original engineer had been a bricklayer, who having developed a partiality for hanging around the boiler, during the construction period, in order to warm himself, was struck by the comparatively easy and sheltered life the fireman seemed to lead. It looked so much more comfortable than laying bricks in the invigorating winter climate, that he determined to change his profession. Fortune favored him, inasmuch as the incumbent of the position developed an attack of the demon rum, and was summarily discharged. The erstwhile follower of the ancient rites applied for the position, and obtained it.

The product of the factory was a household need. With the growing population of the country the demand for the company's goods increased. The plant grew, more power was necessary, and a horizontal boiler took the place of the vertical, a new boiler room being built to house it. More buildings came along, more pipings, more boilers, more power. With the help of the handy man who had become the chief steamfitter, pipes were run here and there and everywhere. With the introduction of motors instead of the old line shaft drive, an electrician became necessary. Old Bill, the one-time bricklayer, kept strictly aloof from this phase of the proceedings. He was already in the position of the Irish Fusilier crossing the Tugela River in the Boer War. The commanding officer, during the fording of the stream, gave the order "Fall in two deep." One of his followers replied in anguished tones, "Begorra, I'm in two deep already."

Things were getting so complicated for Bill, that he decided to find an easier job. Before long he got in touch with a nice little factory that used one boiler for heating only, and transferred his patiently won engineering abilities to this haven of rest. This was where I stepped in.

I was at that time in a big plant out in the country, but yearned for a city life. Some friends of mine in the supply business were looking out for a job for me, and one day I got a letter from them, advising me that some clients of theirs had a nice little plant they wanted a man for, who could do a little re-organizing. After a little correspondence. I accepted the position, and moved in to the city.

I found a plant, consisting of four 150 h.p. horizontal return tube boilers, a pair of compound engines, horizontal, air compressor, belt-driven generators, hydraulic pump, and the old original engine, which was used occasionally at nights.

In the boiler room was the most astounding collection of pipes it has ever been my misfortune to run up against. They ran overhead, under the floor, were mounted row upon row on the walls. The main steam pipe was a fearful and wonderful layout, and a graceful wreath of steam surrounded every joint. While I was standing on the boiler top, trying to visualize this Chinese puzzle, a wildly excited old fellow rushed up the ladder, and started shutting down the main stop valves on all four boilers. Naturally all the safety valves started to blow, and the boiler tops become a most uncomfortable location. The boilers were in the basement, and there was a door leading from the tops to the yard, so I strolled gracefully out to wait for the excitement to stop. I hadn't yet taken charge, and my enthusiasm was beginning to cool a little.

While I was trying to decide on whether I should go home or not, the superintendent came along. He had left me just a few minutes before, to allow me to look around a little. He looked worried. "I thought you were in the boiler room," he barked when he saw me. "Well, I was," I replied, "but there seems to be a holiday proclaimed, and I didn't want to interfere. Does this sort of thing occur very frequently, or is it just emergency practice?"

"Well, this is what we want to stop. All this trouble is over a burst pipe in the galvanizing department. There's so many pipes and valves leading there that no one knows what to shut off, and the quickest way is to shut everything off, plug the pipe, and trace it after."

That was my introduction. However, I liked the super, and was promised very many inducements if I would stay and straighten things out. I stayed, and in a few months had things improved a lot. Incidentally, I had a lot of trouble with some of the oldtimers, especially a night fireman, an Italian. It ended up with my firing him, and he departed, vowing vengeance.

Christmas was approaching, and I was getting over the worst of my troubles. I didn't have to work more than an average of fourteen hours a day, and sometimes even got a Sunday at home. I had been married a short time, and was getting quite well acquainted with my wife, in the intervals between supper and bed.

One day, I was called to the 'phone. A strange voice came over the wire. "Is that Mr.——?" it demanded. I pleaded guilty. "You are chief engineer there?" Again I admitted the soft impeachment. "That's alright. Now what is your private address?"

I immediately became dignified. "I don't know you, sir, and I don't give my address to strangers. Who are you, and what do you want." Mystery pervaded the voice. "You'll find out who I am in good time. I can't tell you over the 'phone." "Very well then," I replied, "it's no use prolonging the conversation."

I hung up the receiver, and tried to forget all about it, but I kept on wondering. It seemed peculiar.

Foolishly, I told my wife about it after supper that night. To my surprise, she immediately dissolved into tears. "Oh dear, oh dear, I knew something awful would happen. Why did you do it?" Not knowing what I had done, I couldn't explain, so said nothing. "Don't you see," she went on, "it's that dreadful Italian. The papers are full of dynamite outrages. We'll be blown up in our sleep, I know we will."

This angle hadn't occurred to me. It seemed funny to me, and I was foolish enough to laugh. I got the blowing up right there, and incidentally, determined to keep business affairs to myself in future. However, peace settled down after a while, and nothing more was said, though she was plainly worried.

Two days after came the call again. This time I had a new idea. "Look here, old chap," I said to the unknown, "I have all the life insurance I can carry, so it's no use your bothering." The owner of the voice laughed. "I am

not selling life insurance, but I'm glad to know you carry it." There was something about this I didn't like. I tried a new tack. "Why don't you come down here and see me?" I demanded. "Oh, that wouldn't do. It's better for my own sake to see you at your house." "Well, you can jolly well find out," I yelled. "I'll never tell you." He laughed again. "I just called you up to let you know I've found out. You'll see me on Christmas Eve," and the receiver was hung up at his end.

Christmas Eve was only two days off. I did a lot of powerful thinking during that time, though I didn't say any more to my wife. I could think of no solution. I didn't owe any money to anyone, and had no enemies, with the possible exception of my late fireman. There seemed nothing to do but wait.

We were going out that night, and though I was not to be scared, I was sort of hurrying my wife up while she dressed. She seemed to be longer than usual, but the last time I looked in she had said she couldn't be any quicker, and I was making her nervous. I thought to myself, that was quite fair, as I was nervous myself.

A short, sharp ring at the door bell. I jumped about a foot, and then, pulling myself together, boldly opened the door. A mild looking stranger stood there. "You are Mr. ——" he asked, and immediately I recognized the mysterious voice of the telephone. I nodded without answering.

"You have given me a lot of trouble to find you," he went on. "Can I speak to you a minute." I sized him up, and concluded I could handle him alright. "Very well, come in," I answered, and led him in to my modest sitting room.

"My name is Brown," he said as he took a chair. "I represent the —— Oil Co. I have been months trying to sell your firm, and shortly after you took charge, I got an order. Here is a little Christmas present," and he laid a ten dollar bill on the table.

I tried to protest. "Not a word," he broke in. "This is entirely between you and me. I wish you a very merry Christmas." Before I could frame the words I wanted to speak to him, he had reached the door, and was half way down the steps. I concluded to let him go, and returned to the room, to enjoy the heartiest laugh I had enjoyed for some days.

My wife came out to enquire into the cause of my mirth. I told her I was laughing at a man for giving me ten dollars. "Of course," she said, "ten dollars is only a joke to you. What was it for?" "Well, my dear, it was supposed to be for value received." I explained what my visitor had said to me. "The whole point is this. I had no more to do with purchasing oil or any other supplies than you have. Our firm divides its orders among the people who buy from them, and no matter what the quality, they each get a turn. Anything I say for or against carries no weight. As a matter of fact, this chap has the worst brand of oil on the market, and he knows it. That's why he feels so grateful to me, for what he thinks is my good influence. It would be a shame to undeceive him. The reason he got an order is because his people bought some stuff from our firm, and as long as they continue to buy from us, he will get more orders, and we will get a visit from Santa Claus."

Well, the following Christmas, I received two ten dollar bills, and the one after that, on the last occasion I showed my friend a case of cutlery the boys had given me that day on the occasion of my leaving the firm.

"Well," he said, "I am sorry you are leaving. I hope you will put in a good word for me with your successor."

I promised.

The Joys of Camping Out

HE thought he'd take some holidays and so he got a tent, to camp beside the babbling brook and save a month of rent. He got some pickles and some ham, some salmon and some tea, and every kind of fodder that his cooking eye could see.

And then he got a tiny bed, a blanket and a sheet, to keep the spiders and the bugs from rompin' on his feet.

He also bought a fryin' pan and took a spoon and knife, and told his friends that he was off to lead the simple life. The boarding house he would forget and all his troubles there, and just commune with nature and devour the clover air.

The day had been so beastly hot, it added to his zest to reach the shady wooded spot and chuck his coat and vest.

The camper ate his humble meal and lined up his interior, and swore, by gum, that campin' was a system most superior. He lit his pipe and in the dusk he puffed great clouds of smoke, and dreamed he wuz an Injun brave 'way down at Shogyhoke.

And then he tumbled into bed to dream of joys in store, and the woods re-echoed for a mile with a most gigantic snore.

And the sun came peepin' in at him and he chuckled out with glee, "By all the jumpin' hottenots, this is the life for me." He made a rush to get a meal just like a hungry horse, for this tentin' in the woods had roused his appetite, of course.

But the ants were in the butter dish, and flies camped on the ham, and fourteen different crawlin' things were in the fryin' pan.

The bugs were swimmin' in the milk, though some of them were dead, and the worms had set up keepin' house inside his loaf of bread. He said a lot of sizzlin' words, they just ran out like strings—he's boardin' by the week again on hash and prunes and things.—Ark.

ONCE the Allies finish up the peace terms the next thing is to polish off the man who started the whole thing. At present he's hiding behind a Dutch bedstead.

* * *

WE are now approaching that peculiar season of the year which is punctuated at painfully regular intervals by rhubarb sauce, rhubarb pie, rhubarb pudding, rhubarb, etc., etc., etc.

* * *

CITIES shove up taxes on vacant land to make the holders sell. Very good. But in so doing they simply put the price of vacant land where the real honest-to-goodness builder can't touch it.

* * *

ON May 7, 1915, the Germans sank the Lusitania, and on May 7, 1919, the peace terms were handed to them. It took four years, but the wind was sown and the whirlwind was the harvest.

* * *

THE box car is the greatest industrial loafer that we have heard of for some time. In fact, some railroad man with a mania for figures has it figured out that if the box car came to work at 10 in the morning the whistle would blow at 12 minutes past 11 for it to quit work. The rest of its time it is hanging around on sidings and waiting to be loaded or unloaded. As there are some 2,500,000 freight cars in United States alone, the amount of loafing this collection does must be staggering in the aggregate.

* * *

OUR idea of a steady job is being janitor of that airdrome in Newfoundland where those trans-Atlantic flyers are going to start from.

Progress in New Equipment

THE BLONCK EFFICIENCY METER

THE illustration shows two Blonck boiler efficiency meters installed on a double boiler setting at the High Level Pumping Station, Toronto waterworks. The use of these meters effects considerable economy wherever installed, and at the same time they are as nearly foolproof as possible. This efficiency meter, if carefully watched, will be sure to bring about an average increase in CO_2. It indicates constantly the condition of the fire and baffles, and in general the clinkers and soot, and is a good guide to damper regulation. All this is accomplished without having to teach the fireman anything more scientific than the relative positions of two different colored oils in a draft gauge. The position of these two columns of oil shows the fireman when his fires are too heavy or too light, or whether he has holes in his fire, etc. More than this, they show how the furnace is operating and if there should be an accumulation of soot on the tubes, or if a baffle falls these things will be indicated in an unmistakable manner.

The meter is always calibrated with the boiler, to which it is fitted, and CO_2 analyses taken to determine the best operating condition of the boiler on normal rating. When this is determined the two different colored liquids will be found to be in alignment and at the proper point on the scale for normal load. Should a lighter fire than normal be carried for light load conditions, the liquid columns still in alignment if the proper conditions are maintained will be to the left of the normal operating position, and if a heavier load than usual is carried, to the right.

The meter is applicable to both forced draft and natural draft conditions, and the pipe connections are easily arranged for either condition. In addition to the running of pipe connections the boiler damper should be arranged in such a manner that it can easily be adjusted from a position near the meter.

The meter is easily checked up for accuracy by removing two plugs and letting the two liquid columns return to zero. Should they not return to zero the meter is easily readjusted by placing more of the proper colored oil in until they do.

A Fuel Saving of Almost 10%

The figures given below are from four ten-hour shift tests, made with 4 Sterling boilers, identical in every respect, two equipped with Blonck boiler efficiency meters, and the other two running without them.

All four boilers were running at the same time, thus eliminating all atmospheric changes, and all four were fed from the same bunker.

These tests were made in May, 1918, by the engineers of one of the largest and best equipped plants in the United States, the plant being furnished with all known devices for efficiency and saving:

	Without Blonck Meter	With Blonck Meter
Aggregate duration of test hours	40	40
Feed water, pounds.	1,539,451	1,677,455
Feed water temperature, deg. fahr. .	91	91
Coal as fired, pounds .	274,815	287,100
Steam pressure, average	137	137
Evaporation per lb. of coal from and at 212 deg. fahr. .	6.15	6.82
Percentage of saving		9.83%

The meter representative had no connection with these tests except to set the narrow plates of the Blonck meters for best firing conditions.

After that was done, the running of the tests was left entirely to the firemen and engineers of the plant, and the data as above quoted represent the results obtained as shown by their own figures.

E. J. Philips and Sons, Hamilton, Trust Bldg., Toronto, have been appointed sole Ontario representatives for this meter.

BLONCK BOILER METERS.

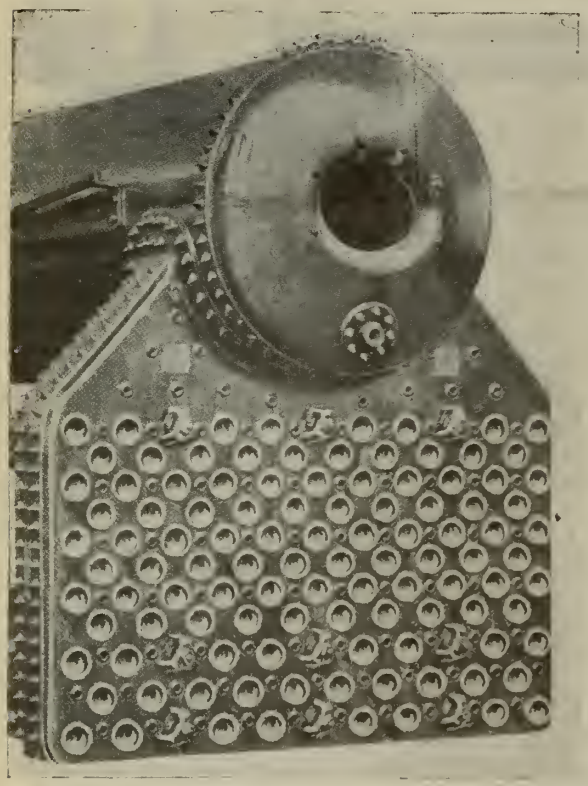
HANDHOLE CAPS

The accompanying illustration shows a new device which has met with considerable success for the capping of tube holes in water tube boilers, superheaters, down draft furnaces and other special apparatus. The Key Safety handhole cap is a pressed steel cup with tapering sides, and is placed in position from the inside of the boiler. In applying it all of the handhole openings are first converted to a standard size by revolving in the hole a special roller tool. As the rollers revolve they remove any roughness from the interior diameter of the holes, and impart to it a taper corresponding to the taper of the cap.

The handhole caps, after being coated with graphite cement, are lifted into the holes by a special pickup, attached to a chain from inside the water leg. When the rollers of a setting tool are revolved inside the open cup face of the cap, thereby pulling the cap tightly into the hole, and making a metal to metal contact which will stand more than 3,000 lbs. to the sq. in. on hydrostatic test.

In operation the steam pressure on the cap holds it on its seat like a check valve, and when necessary to remove it a blow with the hammer readily unseats it.

This device is applicable to many other uses besides the one illustrated. Old fire tube boilers may easily and cheaply be converted into serviceable tanks through the medium of closing up the tube holes with the handhole caps.



HANDHOLE CAPS.

This handhole cap is sold in Canada by the Power Plant Equipment Company, Ltd., Toronto.

THE NEW ONE-UNIT TURBO CENTRIFUGAL BOILER FEED PUMP

Ever since specially designed centrifugal boiler feed pumps have demonstrated their efficiency and economy in power plants of modern construction, the owners and operators of smaller power plants have been waiting for a centrifugal boiler feed pump which would meet their requirements.

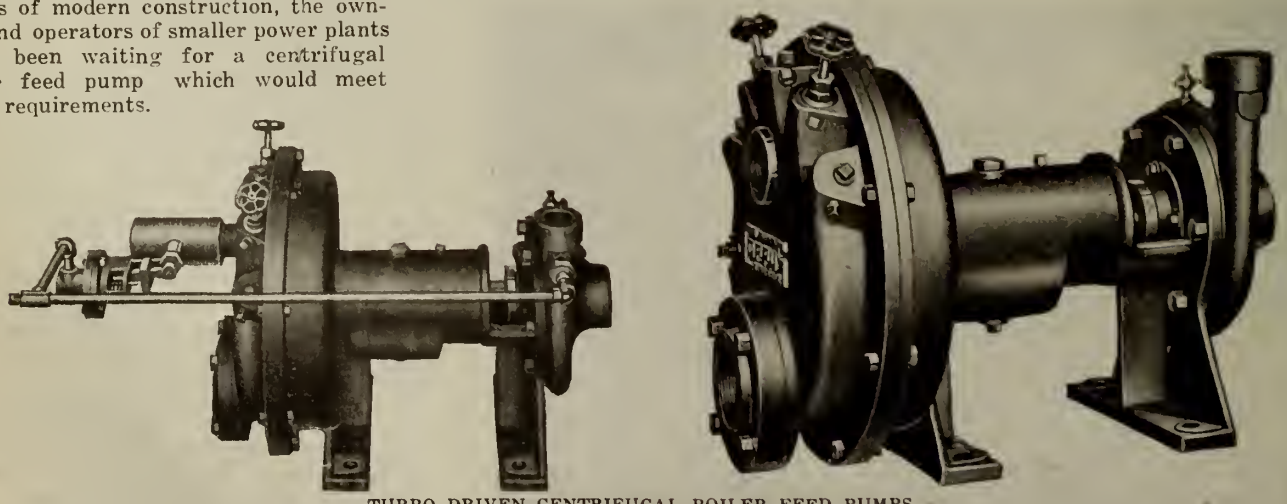
The only reason that such a pump has not been constructed up to the present time is the fact that practically all pump manufacturers specialize in pumps alone. Since they do not build either steam turbines or electromotors, the driving end of a centrifugal feed pump could not be constructed in the same plant as the pump. This necessitated the two-unit type of construction, involving a more expensive product than most small power plants are willing to invest in.

A manufacturer of small power turbines has just placed on the market a new steam turbine driven centrifugal boiler feed pump, especially designed for boiler feeding, in plants of 100 to 3,500 b.h.p. Every care has been taken to see that all the advantages of centrifugal feed pumps which have proved so successful in larger plants, have been retained in this smaller, more compact unit.

Both the pump and the steam turbine are combined in a single unit, and thus the pump occupies but very little floor space. Simply designed, compactly constructed of the best materials, in a plant newly equipped for the purpose, the new pump promises to come into general favor in a very short time.

As with larger centrifugal boiler feed pumps, the exhaust steam is free from oil, there is no water hammer so injurious to pipe lines and valves, and the steam consumption is unusually low. The feed water capacity is controlled by regulating the hand valves at the boilers, a saving of time that will be much appreciated by any power plant engineer.

The pump is built in four standard sizes, in capacities ranging from 100 to 3,500 b.h.p. Full details and an interesting catalog will be sent upon request by the Coppus Engineering and Equipment Co., 344 Park Ave., Worcester, Mass.



TURBO DRIVEN CENTRIFUGAL BOILER FEED PUMPS.

"POWER HOUSE is instructive and contains good information." — Mr. F. Roseburgh, Toronto.

DURABLA PACKING

Flange joints in piping installations are factors in engineering that demand particular attention, especially where the system is operated under varying conditions of heat and cold, and the consequent expansion and contraction of the metal, and the condensation of the steam and vapors. Economy should never displace efficiency unless this efficiency means economy.

Durabla packing is made of a combination of asbestos and the best binding materials, which will not pulp around the joint. It is unaffected by temperature change, or the action of oils, chemicals, hot water and liquids, and gives exceptional service for steam and gas engine operation. It has a peculiar ability to withstand shock or vibration, which makes it very effective for steamship service. It is made in sheet or gasket form and will withstand temperature of 1,000 degrees and pressure of 300 lbs. without signs of destruction, and will not deteriorate when kept in stock for a lengthy period.

DURABLA PACKING

"Your ads. are read as much as the other matter."—Mr. G. Newton, Winnipeg.

"I look over the advertisements the first thing for new machines or new advertisers. I thereby learn something about machines."—Mr. Lamb, Goderich.

"I can say that POWER HOUSE is a helpful paper for me, and that I never will be without it so long as I am an engineer."—Mr. J. D. Barkman, Steinbach, Man.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Readers are invited to send in answers to these problems, as they have been chosen for their interest and application to the practical side of power plant operation.

Perhaps you, too, have some pet problems, or hard nuts which you would like to ask your fellow engineers; if so, send them along for the benefit of others.

Answers, together with the original question, will be published in the issues following the appearance of the question.

Questions Before The House

13. If your safety valve has been blowing off at 100 lbs. and now commences to blow at 80 lbs., what would you do to remedy the same, in the event of the steam gauge indicating 120 lbs. before the safety began to blow? What would you consider the possible cause, and what would you do to remedy the same? What action would you take?

14. If you were taking charge of a boiler where the safety valve steam gauge and water column had been taken off to prevent damage to same, and you were in doubt as to the correctness of the steam gauge, how would you set the safety valve when it was replaced on the boiler in order that it might blow off steam at 100 lbs. pressure, and in replacing the water column how would you set it at the correct height on the boiler?

15 .Explain the construction and action of an expansion joint as used on a main steam pipe. What omission in the construction of expansion joints would lead to serious accidents when steam is first applied?

16. Explain fully the construction and action of a safety valve spring-loaded pop. In what does it differ from the other ordinary spring-loaded valve? What is the advantage of the pop over the ordinary? How does the connecting of a long discharge pipe affect its working.

17. What is the meaning of factor of safety as applied to steam boilers? What is the real limit of the strength of a boiler? Explain the manners in which frequent variations of steam pressure affects the strength of boiler, and why?

18. Show by sketches and explain different ways of staying the segments of boiler heads above the tubes, stating the advantages and disadvantages of each method?

19. What is the difference between a direct current dynamo and an alternating current dynamo? In what way does a dynamo differ from an electric motor? Can a dynamo be run as a motor, or the motor as a dynamo?

20. If you were in charge of a steam plant where there was boiler power to spare, but the engine in its present condition was fully loaded, what would you do to increase the power of the engine in order to run extra machinery, assuming that the boiler pressure can not be raised, and that all parts of the engine are strong enough to carry the extra load?

21. Explain some type of ammoniac compressor, giving details of operation. How would you naturalize ammoniac fumes escaping from a leaky pipe in an enclosed room, and after this is done how would you locate the leak?

22. What is the safety head of an ammoniac compressor? What purpose does it serve, and how is it constructed? What precautions are necessary in taking compressor cylinder apart in order to prevent injury from inhaling ammoniac gas, if this gas should be inhaled to such an extent that a person becomes unconscious, what action would you take to save him?

23. What is the position of the eccentric related to that of the crank for engine running, either over or under (a) with direct motion; (b) with indirect motion; (c) with indirect valve and direct motion; (e) with expansion valve (righting cut off) direct motion, with indirect motion for same?

E. V. M., Lardo, B.C.

Answers to Questions In Last Issue

Question 9.—What is the probable h.p. of the following engine, also the water consumption per h,p, hour, the boiler h.p. and the size of the feed pump required to supply this outfit with water. The engine is non-condensing and compound, having cyls. 11 in.×19 in.×12 in. stroke, running 260 r.p.m. cut-off H. pressure ⅝ stroke, and cutoff L. pressure ¾ stroke.

Answer.—First we will have to assume some definite pressure, say 100 lbs. gauge. Now to find the mean forward pressure in the high pressure cyl. use the following formula:

$$Pm = P\frac{(1 + \text{Hyp. log } R.)}{R} - \text{in this case}$$

$$115 + \frac{(1 + .4700)}{1.6} = 105.8 \text{ lbs., the mean}$$

forward pressure.

(The ratio of expansion in high pressure cylinder = 1.6, hyperbolic logarithm of 1.6 is .47000.)

Next we must find the back pressure against the high pressure piston on the receiver pressure. This may be found as follows:

115 lbs. ÷ 15=7.6, the ratio of expansion throughout the both cyls. and the square root of 7.6=2.7 approx., and 115 ÷2.7=42.6 lbs. pressure approx. Now 105.8—42.6 = 63.2 lbs. × .8 as a factor equals 50.5 lbs. as the mean effective pressure in the high pressure cyl.

It is good practice to have the range of temperature drop in each cylinder about the same. So we will see how this works out. Steam at 115 lbs. =338° F. approx. and at 15 lbs. 213° F. Now 338 − 213 = 125°÷2 = 275.5° F., and as 275.5° F.=16 lbs. pressure, this receiver pressure should be O.K.

Now the M.E.P. in the low pressure cyl. is found in the same way.

$$Pm = P\frac{(1 + \text{Hyp. log. } R)}{R} \text{ or}$$

$$42.6 \frac{(1 + .2626)}{1.33} - 15 = 25.5 \text{ lbs.} \times .75 \text{ as}$$

a factor = 19 lbs. approx., as the mean effective pressure in the low pressure cyl.

$$\text{The horsepower} = \frac{\text{PLAN}}{33{,}000}$$

For the high pressure cylinder this equals:

$$\frac{50.5 \times 1 \times 95.3 \times 260 \times 2}{33000} = 76 \text{ h.p. approx.}$$

and for the low pressure cyl. this equals

$$\frac{19 \times 1 \times 283.5 \times 260 \times 2}{33000} = 83 + \text{h.p. approx.}$$

Now the total equals 78+83 = 161 h.p.

The steam consumption of engine, with say, 2 % clearance in high pressure cyl. and neglecting the piston rod and condensation in pipe lines and ports, equals:

$$\frac{95.3 \text{ sq. in.} \times 12 \times ⅝ \text{ of stroke} - .02\%}{1728} \times$$

$$.2617 \times 2 \times 260$$

or 55.8 lbs. of steam per minute, and 55.8×60=3448. lbs. of steam per hr., and 3448÷161. h.p.=21.4 lbs. of steam per h.p. hour.

(Quite an economical engine if it really develops the 161. horse power.)

Now taking 30 lbs. of steam to equal 1 b.h.p. this engine would require 115 h.p. boiler, or better, 125 h.p., this boiler would require a pump, if it is to handle hot water. A steam cyl. 4½ in. dia., water cyl. 3 in. dia., length to stroke 4 inches, this pump to be of the duplex ram pattern.

NOTE.—This problem has been solved throughout by the use of a slide rule, therefore is only approximately correct.

F. F. McNEIL.

Question 11.—A cyl. 24 in. bore, carrying an initial pressure of 100 lbs. gauge, the studs to hold the cyl. head in place have an allowable pressure of 5,000 lbs. per sq. in. section. How many studs and at what pitch would they be placed?

First the thickness of cyl. walls should be approx.

$$t = 0.0004\ D\ p + .03 \text{ in.}$$

When t = thickness of wall in inches

D = dia. of cyl.

p = maximum pressure lbs. per sq. in. allowing 12,500 lbs. tensile strength of cast iron and 10 as a factor of safety, with .03 in. for reboxing.

This would make the diameter of the circle for bolts equal to about 27½ in. and $.24 \times .7854 \times 100 = 45{,}240$ lbs.

Now if we would take the area of one bolt as equal to 1 sq. in., this would only require 9 bolts, which is not sufficient. Better to make bolts smaller, say 1 in. in dia., area of 1 in. = .7854 × 5000=3927 lbs., that can be carried by one stud.

Now 54240÷3927=12 studs required approximately.

Now as 27½ in. is the dia. of the stud circle, the pitch of studs will be $27.5 \times 3.1416 = 84.8 \div 12 = 7.06 + 1$n., circular pitch, not chordal pitch.

F. F. M.

Question 12.—The stays in a horizontal tubular boiler have an allowance of 6,000 lbs. per sq. in. If the segment to be stayed is 24 in. × 72 in. what is the dia. and the number of stays required?

Answer.—Now, 24 in.—2′=20 in. and 72—2′=68 in.

$$\text{Area of segment} = \frac{20,^3}{68 \times 2} = 58.8$$

and

$$\frac{68 \times 2 \times 20}{3} = 906.6$$

Total area 965.4 ins.

Area of segment to be supported is, therefore, 965.4 sq. inches.

Again we will have to assume some definite working pressure, this pressure will be governed by the weakest part of the boiler. Say 125 lbs. working pressure.

Now 965.4×125=110,675 lbs. to be supported. The number of stays at this 6,000 lbs. would be 110.675÷6000=18.3 stays of 1 sq. in. area, or say 18 stays. The diameter of the stay if made of round steel would be 1⅛ in. approx.

If stay is made of flat bar it must have the same sectional area and the "crow feet" to have the same sectional area as the body of stay after the rivet holes are drilled.

NOTE.—All of the above questions have been solved by the use of a "slide rule," so are only approximately correct.

F. F. McNEIL.

Readers' Queries

Question.—What horsepower should a Woolf reverse compound engine develop? High pressure cylinder, 7¼ in., low pressure 11 in. diameter, 10 in. stroke, 230 kw. per minute; 150 pounds boiler pressure. What would be the mean pressure in the high and low pressure cylinders? What back pressure would there be on the high pressure piston? How much more power would the same engine develop with 175 pounds boiler pressure?—S.A.P., Hillseby, Sask.

Answer.—You do not give the particular which is the most needed to answer this question, namely, the cut-off in the high pressure cylinder. You should also state whether the engine is tandem or cross. However, assuming your engine cuts off at ¼ stroke in the high pressure cylinder, and that there is a receiver between high and low, the answer would be: Initial pressure, say 140 lbs. at high pressure steam chest. If cut-off takes place at ¼ stroke, ratio of expansion is 1 to 4. Final pressure at release in high would be

$$140 \div 4 = 35 \text{ lbs.}$$

When the exhaust opens the pressure will drop to say 25 lbs. on entering receiver. This will be initial pressure on low pressure piston. As steam is admitted to low pressure cylinder this pressure will drop till admission is cut off, the amount of drop depending on the point of cut-off in the low pressure cylinder.

The amount of power developed in the engine depends entirely on the amount of steam admitted to the high pressure cylinder. The point of cut-off in the low merely alters the distribution of work in the two cylinders, for at whatever point admission to the low pressure ceases, the total weight of steam acting on the engine is the weight admitted to the high pressure at cut-off in that cylinder. If the cut-off in the low is early, more work will be done in the low, and less in the high, and vice versa. The ratio of the cylinders is in the proportion of $7\frac{1}{4}^2 : 11^2 = 1 : 2.3$. The cut-off in the high is at ¼ stroke. The total expansions are therefore $4 \times 2.3 = 9.2$. This would give a final pressure of about 15 lbs. at release in the low pressure cylinder.

These pressures will be lower in actual practice due to losses. So we have for the high pressure an initial pressure of 140 lbs., and a final pressure of 35, with a back pressure of say 25 lbs. This will give a mean pressure in the high of approximately 62 lbs. The initial pressure in the low will be the receiver pressure, 25 lbs. Final pressure, say 12 lbs., and back pressure about 2 lbs. Mean pressure, say 16 lbs. The M.E.P. referred to the low will be

$$\text{MEP of High} + \text{MEP of Low} = 62 + 16 =$$

$$\frac{\text{M.E.P. of High}}{\text{Ratio of H to L}} + \text{M.E.P. of low} =$$

$$\frac{62}{2.3} + 16 = 43 \text{ lbs.}$$

$$\text{H.P.} = \frac{43 \times 11 \times 11 \times .7854 \times 10 \times 2 \times 230}{12 \times 33{,}000} = 47.46$$

Your engine would be about 50 h.p.

Increasing the pressure to 175 lbs., keeping cut-off the same, would increase the power about as follows. The initial pressure at high becomes 165 lbs. Final pressure 41.25 lbs. Back pressure about 30 lbs.

In low initial pressure 30 lbs., final pressure 18 lbs., back pressure 3 lbs.

M.E.P. of High=73 lbs. M.E.P. of low 20 lbs.

$$\frac{73}{2.3} + 20 = 51 \text{ M.E.P. referred to low.}$$

$$\frac{51 \times 11 \times 11 \times .7854 \times 2 \times 10 \times 230}{33{,}000 \times 12} = 56.3$$

These calculations are necessarily approximate, but illustrate the methods employed. The only real determination is by the indicator.

WASTED FUEL IN FACTORIES

In most factories the ashes and waste from boiler and other furnaces, carrying a variable amount of usable fuel, is either taken to a common dump or is carted away without any attempt at recovering the useful parts, sifting even not often being done. In this way loss of fuel occurs, and it would seem that there is room for treatment of both factory and domestic fuel wastes. Probably a combination of dry and wet separation would give the best results, the material being graded and to some extent separated dry by means of revolving screws as in a coal washery, and afterwards separated in wet jigging or other machines so far as the heavy waste is concerned, the light stuff, metals and other material over, perhaps, rejections from a 2 inch mesh screen, being hand sorted. Fine stuff below that passing a ¼ inch mesh screen could also be left untreated, and the result of treating the grades between the ½ inch and 2 inch would be fuel and waste.—M. M.

J. Patterson, superintendent of works for the Shell-Bar Boico Supply Co., Ltd., Toronto, died on the 23rd of April. Mr. Patterson was extremely well known in engineering circles, and for the past four years had been works manager for the above firm.

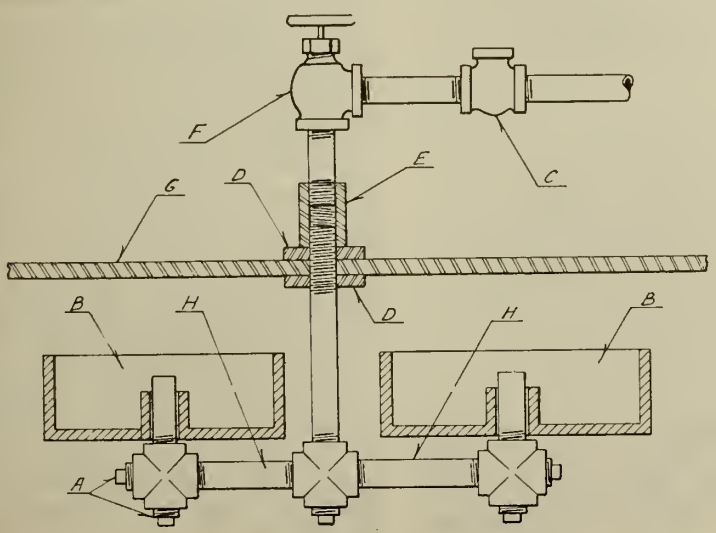
The American Steam Conveyor Corporation, Chicago, announce the appointment of N. B. Stewart as district representative in charge of their St. Louis territory. Offices have been opened at 708 Merchants LaClede Building, St. Louis, Missouri.

The Operators' Point of View

TOP FEED PIPE FOR DIRTY WATER

THE feed arrangement shown is an improvement over the scale box usually placed on top row of boiler tubes. Three cross ties are connected as shown with cleanout plugs, A, screwed in just tight enough to prevent them unscrewing by any slight vibration that may occur. Two short upright pieces of pipe are turned into the upper outlet of the end ties. The centre upright is connected to the top of the boiler shell with two locknuts, D D E. is a pipe coupling. F an angle valve and C a check valve. B B are two shallow cast iron boxes, with an opening in the centre as shown. These boxes can be made about 20 inches long, by 12 inches wide, by 5 inches high, for a boiler 60 in. x 16 in., or smaller. The pipe arrangement must be placed just low enough to allow the boxes to be lifted from the centre pieces. The pieces H H must be screwed in very tight, so that the weight of the boxes will not cause them to unscrew and allow the boxes to fall off.

The feed through the double pipes will be so slow that much of the dirt will settle in the boxes, which can be taken out and emptied at cleanout time. All the pipes should be full size. Boilers from 42 to 54 in. in diameter should have a feed pipe of 1½ inches; boilers 60 in. in diameter should be 2 inch. Of course pipes a size smaller than this will supply the water required so long as they are free of scale, but it sometimes proves a paying investment to use pipes a size larger than actually necessary. One objection which has been held against the scale box was placing it on top of the tubes. The scheme shown gets away from this.—J. E. NOBLE.



TOP FEED FOR DIRTY WATER.

SOME INTERESTING BELL CONNECTIONS

By R. S. WRIGHT

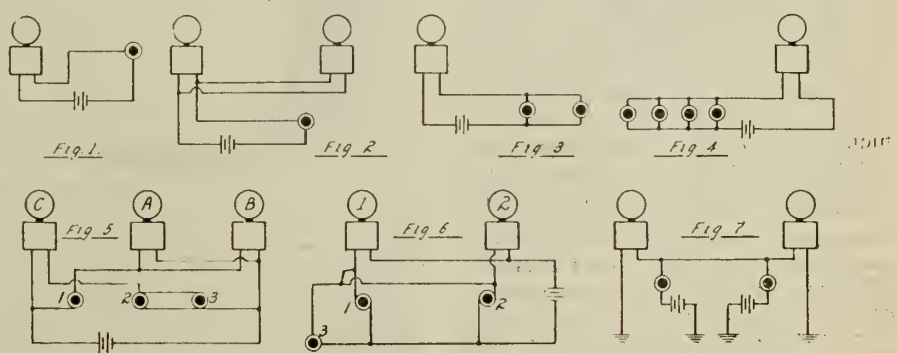
The method adopted for running the wires of bell circuits will depend upon the character of the installation, involving the complexity of the system. Fig. 1 shows a very simple bell circuit, composed of bell, single contact push button, and a battery. The circuit is closed by pressing the button, then the current will flow from the battery through the bell and push button, and back to the battery, causing the bell to ring as long as the button is pressed. This system is suitable for a front door bell.

Fig. 2 shows how an additional bell can be connected in parallel with the bell in Fig. 1. In this circuit both bells will ring when the button is pressed, the current dividing at the point where the bells are connected together.

In Fig. 3 two buttons are connected in parallel, and either will ring the bell. This circuit shows how the bell may be rung from either front or back door.

Fig. 4 shows four buttons connected in parallel either of which will ring the bell. The circuit is used when it is desired to ring the bell from four different points.

Fig. 5 is a combination of Figs. 2 and 3. Push-button No. 1 will ring bells A and B, which are connected in parallel. Buttons Nos. 2 and 3 are in parallel and either will ring bell C.



BELL CONNECTIONS.

Fig. 6 shows a circuit where one single contact and two double contact push buttons are used in connection with two bells in parallel. Double-contact push buttons are used for the purpose of saving wire. Without them, in a circuit, more wire would have to be used to get the same result. No. 1 button will ring No. 1 bell; No. 2 button will ring No. 2 bell, and No. 3 button will ring both bells in parallel.

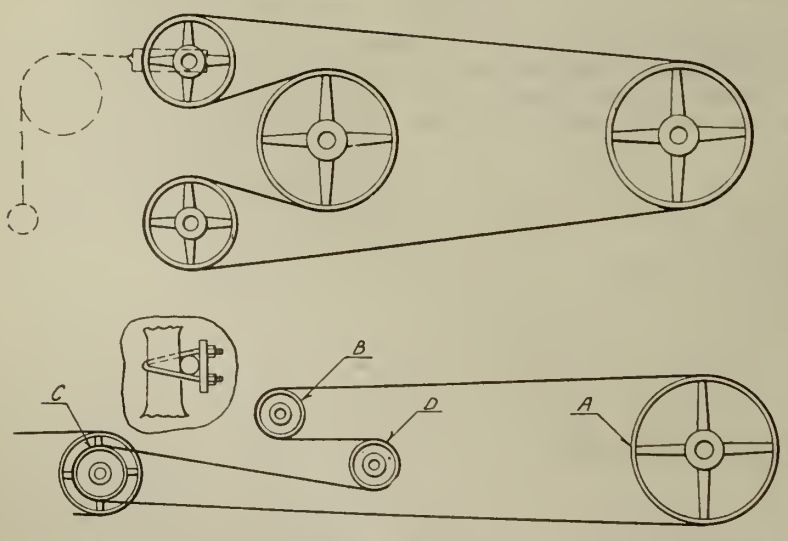
Fig. 7. This circuit shows a ground return. Any bell-circuit using a wire for the return is called a metallic circuit. Any circuit where the ground is used as a return is called a ground circuit. In general it makes no difference whether the positive or the negative pole of the battery connects with the bell or the push button, except where a ground return is used. In the latter case the negative pole should connect with the earth. Ground wires are usually connected to ground-plates, but it is very common to use a gas or water pipe where convenient as a ground return. It should always be remembered that the positive pole of the batery is at the top of the negative plate and the negative pole is at the top of the positive plate. For in-

stance, in the case of a Leclanche cell, or dry cell, the positive pole is at the top of the carbon (negative) element, and the negative pole is the top of the zinc (positive) element. In the case of a gravity Daniel cell the positive pole is at the top of the copper (negative) plate, and the negative pole is at the top of the zinc (positive) plate. Within the cell the electric current always flows from the positive plate to the negative plate, while in the external circuit the current always flows from the positive pole to the negative pole of the cell or battery.

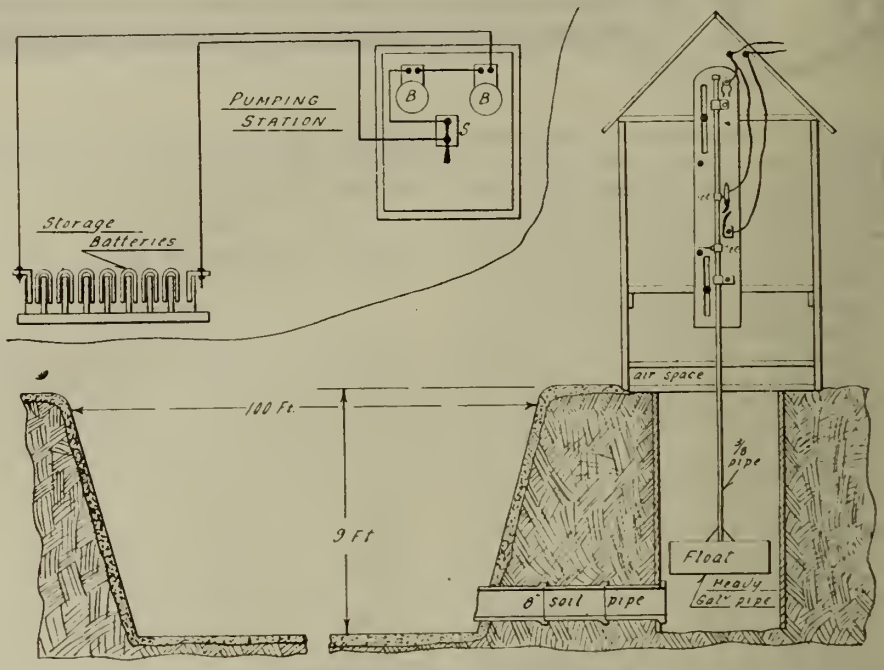
REVERSED BELT DRIVE

Some months ago a contributor to POWER HOUSE described a rather out of the ordinary type of belt drive, like that shown in Fig. 1. The advantages inherent in this type are (a) where reversal of rotation is desired this does not wear, chafe, or burn the belt as does a crossed belt drive, especially where there is a wide ratio between the diameters of the two pulleys used, and (b) when the shaft centres are not far apart and the load is considerable, in which case a short cross belt depreciates rapidly and is also hard on the bearings. The dotted lines in Fig. 1 indicate the possibility of using one of the idlers as a unique application of this drive as I once saw it used in a portable sawmill, and which is perhaps equally applicable to some other lines of work. By way of explanation I will mention that these plants are essentially ground floor installations, and that when an edger is used it is customarily driven from a pulley on arbor of the lumber saw. This arbor is some feet longer than that used in two story mills, or, when not itself longer, it is provided with an extension which gives the same result. The slab saw is customarily driven from an overhead line shaft, which in turn is driven from a second pulley on the engine crankshaft. By this method the slab saw table lies cross-wise of the mill. Sometimes a quarter-turn belt or a bevel gear or a bevel friction is inserted so as to enable the millwright to place the slab saw table lengthwise of the mill, thus making easier work for the slab saw man. In many instances no trimmers are installed. In this particular plant there was only one pulley on the engine crankshaft, and not enough remaining for a second one. Then, too, the overhead line shaft was too short for the customary drive unless a quarter-turn belt were used, which, however, would normally have required the second pulley on the crankshaft. Fig. 2 indicates the layout they finally adopted. A is the pulley normally used for driving the edger. B is the edger pulley. C is the slab saw line shaft pulley (this is the shaft which is normally placed overhead and driven from the crankshaft.) This was, in this instance, placed low down and the slab saw driven from it by a horizontal instead of a vertical belt. The slab table ran cross-wise of the mill. By means of twisted U clamps (see insert Fig. 2) the millwright clamped across the edger frame a piece of 1 15-16 shaft, about the length of the edger arbor, and on this he placed the loose pulley, D, held securely in place by a reliable collar on each side of it. By belting the pulleys as indicated (Fig. 2) he thus drove both B and C with the same belt, and avoided the necessity of crowding a second pulley onto the short crankshaft or substituting from the main saw arbor. The plan seemed to give entire satisfaction, though I thought that had the heaviest work been on C instead of on B there would have been some loss of power through D. Others did not all agree on that with me, yet in making similar drives in other types of plant this feature might be worth some consideration, and, if a dynameter or if electric drive were available for use, possibly some experiment could be made.

J. E. McCormack.



REVERSED BELT DRIVE.



ELECTRIC SIGNAL FOR RESERVOIR.

ELECTRIC SIGNAL FOR RESERVOIR

By G. D. Mills

About seven years ago I installed an electric signal for the town of Sussex, to tell the height of water in the reservoir. The pumping station is situated in the town and the reservoir is about a mile away on a side hill.

Before the installation of this signal it was necessary for me to walk up to the reservoir every other day. Sometimes I would find the water very low, which was bad for fire fighting, as may be imagined, and at other times it was running over, causing a waste of fuel.

The accompanying illustration shows a signal which I installed at the pumping station and reservoir. Before installing the signal I knew it would have to be of such a nature as would work in both winter and summer, as the committee would not sanction one for summer use only, the cost of the pole line being quite an item. It was neces-

sary then to figure out how one might be arranged to work with four or five feet of ice in the reservoir. At last the idea struck me, and telling the committee that it could be arranged to work all the year round, I readily obtained permission.

The accompanying sketch shows how the signal system was finally worked out. An eight-inch tile soil pipe lead into an upright shaft in which the float was placed. The float will carry 60 pounds without sinking. The contacts are made of brass and are quite long, so that there is splenty of spring to them. They have also a cutting edge for removing frost if any gathers. The plank carrying the fixtures is provided with slots so that it can be adjusted up and down. The contacts are arranged the same way. We generally keep the low-water mark about 26 inches below high-water level.

The tank which the building sets over is frost-proof so there is no ice to interfere with the operation of the float. First there is a plank floor and then a 10-inch air space, then second floor, then a layer of straw over that, and the building is well banked outside in winter.

Now you notice in the sketch that two vibrating bells are placed on the panel in the pumping station. The second one was installed in case the first should get out of commission.

The line running from the pumping station to the reservoir is a metallic circuit and having eight cells in the battery, which is charged up when charging the fire-alarm system.

This signal has been working for the last seven years and never gives any trouble. I have seen different electric signals for tanks and reservoirs, but none that would work where there is ice.

HARDNESS AND WEAR

Hardness is a metallic quality which practically defies definition; anyhow, recent attempts to define it are, to say the least of it, disappointing. Unusual cases of wear always provide interest to the engineer, and have a bearing on the subject; most often alteration in the material of one member provides a remedy.

In a milling machine of good U. S. A. type there was a worm and wheel meshing. A few days in service found trouble; examination showed that both worm and wheel had the tried and worn appearance as if abrasive had been used for lubricant, the teeth of the wheel were over one-third worn away and the worm itself scored.

The cause—steel worm and steel worm wheel both unhardened; the wheel was replaced by one of cast iron, and gave no subsequent trouble.

In another instance a hand-actuated toggle press of simple type to stretch pieces of solid drawn tube to a shape unobtainable commercially was designed; at all events, although quotations were invited in several likely quarters, none were received, the quantity was moderate, and probably would not pay for special tools and usual drawing methods. Whatever the reason, it was decided to have the job home-made, and a simple toggle drawing press was made up from available material. The screw was fixed at 1¾ in. diameter, for the reason that the shop possessed a pair of R. and L. square thread taps of that size, which were dug out from obscurity; and were a veritable find. The smith was commissioned to make two nuts and blank for threading, and no one gave a thought to material. The smith made screw blank nuts from the same steel bar. It took exactly twelve hours' work to produce fine steel powder, visible on screw and exterior of nut, and lubrication had no effect whatever, while turning the handle became a matter of horsepower. The job was dissembled, the screw cleaned up, and two gun-metal nuts obtained from a local foundry to a hastily made rough pattern. The job never gave trouble after, and the press used for occasional jobs has screw and nut threads in perfect condition after a lapse of years. The question of wear is not altogether one of hardness, M. steel and cast iron work perfectly together as a wearing surface, so also do the usual babbitt and bronze; but a mild steel shaft will not work with a mild steel bearing—try it and see. The shaft will cut and score, while if the pressure is considerable, as in a worm or pressure screw, the freezing qualities of the similar material in contact merely emphasizes the matter. Lubricant has literally no effect whatever; it is merely a vehicle to float away the disintegrated particles of steel as they are produced. Two pieces of steel glass, hard and perfectly polished, might slide for years, but such an instance is, to say the least of it, unusual in mechanical matter. Cast iron, as a wearing surface, is a puzzle. In engine cylinders, worn to a glassy surface, there are minute pin-holes, and a close examination shows that the harder points in the structure stand in relief. The essential beauty of cast iron as a wearing surface is the glaze or surface it acquires after running in under proper treatment. If from any cause the glazed surface, becomes abraded the cast iron wears with great rapidity, scores and cuts up in a remarkable manner. Whether the material actually has a surface flow and gets an increased skin tension analogous to that produced in a fluid when solvent substances are introduced it is impossible to say, although theories to explain the facts are numerous enough.

The glazing property of cast iron is not without drawbacks. Possibly the largest single surfaces exposed to running wear in cast iron are those in the reciprocating marine engine. Guides, slide valves and cylinder surfaces are all of considerable size, and the glazing is very marked. Cast iron is by no means the hardest of known substances, but its resistance to abrasive wear places it in the forefront of substances used by the engineer for wear resisting. This lends interest to the subject of hardness versus abrasion.

The glaze on cast iron after prolonged wear is extremely hard; in fact, on a large slide valve it can hardly be touched by a file under all the pressure a man can exert to make the implement bite.

When a large slide valve on a marine engine gets into this condition, efficient lubrication becomes difficult; at all events, there is a decided tendency for the valve to squeak, and the trembling of the eccentric rods show that it is difficult to propel. Usually high flash cylinder oil in quantity fed by a mechanical lubricator will not effect a cure. The only remedy is to break up the surface of the valve at the earliest opportunity, and every marine engineer is aware of the necessity and deplores the hard work involved. The breaking of the skin on the valve with coarse block files does the trick, while the seating is very rarely touched, except that at long intervals it becomes necessary to remachine both valve and coat. It appears, therefore, that under conditions of large area and considerable pressure with the temperature usual to steam practice, that the skin of machined cast iron undergoes a molecular change, beneficial up to a certain point and then detrimental to running. The same remarks apply to the large guide surfaces and crosshead slippers.

STATE CONTROL OF U. K. ELECTRIC SUPPLY RECOMMENDED

The Advisory Council to the British Ministry of Reconstruction have made a most important and far-reaching recommendation in regard to the nationalization of electrical supply and plant. The report of the chairman recommends:

1. That the electrical power should be generated on a national system.

2. That the operation of large generation stations be taken in hand at once.

3. That generating plant should be nationalized.

4. That distribution should be left in the hands of such of the present agencies as are efficient and progressive.

5. That an Electricity Board be formed, with six members of proved business experience.

The report states that while fully sensible of the necessity of limiting to the utmost extent any further capital commitments of the State, stress is laid upon the vital importance of a full development of electric power for productive purposes. It is pointed out that the development of such power in the United Kingdom is at the present in its infancy, and that high authorities have estimated the loss incurred by the nation through failure to take full advantage of electrical progress at not less than £100,000,000 a year. On the other hand, the capital invested in electrical generation (as distinct from distributing) plant in the United Kingdom does not apparently exceed £45,000,000.

POWER ALCOHOL

By M. M.

The subject of power alcohol is of great importance for two reasons: First, because the world is using the existing limited supply of mineral oils faster than their rate of production, and secondly, because the production of denatured alcohol is an important and profitable industry. The problem naturally falls into two parts: that of production and denaturation, and that of utilization. In Germany the potato is the chief source of the supply, and in 1913 some 70,000,000 gallons of alcohol (90 per cent. absolute) were distilled from potatoes 3,000,000 tons being used for the purpose out of a total crop of 50,000,000 tons grown on over 8,000,000 acres of land. The industry in that country owes its success in part to a bonus on alcohol used for other than beverage purposes (which is provided by a tax levied on the latter) and in part to efficient co-operation between the farm, distillery, and market. In France the chief raw material is beet. In 1912, 18,000,000 gallons of denatured spirit were produced, but the industry was handicapped by the onerous regulations governing the denaturation. These regulations made the spirit expensive and unsuitable for the lighting and internal-combustion engines. Apparently they have been withdrawn since the war began, and it is the intention of the French Government to make alcohol a cheap national motor fuel. Even in the U.S.A. steps are being taken to develop the alcohol industry; in the United Kingdom it hardly exists. In 1914 only 7.7 million gallons of denatured spirit were manufactured, and there is no record that any of it was used for light, heat, or power. In 1915 Great Britain imported 120,000,000 gallons of petrol, and the equivalent quantity of alcohol might easily have been produced in Great Britain. Five million tons of potatoes only would be necessary, and 600,000 acres properly cultivated to yield 12 tons per acre would have provided the crop for food and for alcohol. Beet could be grown instead if it were desirable. The Australian committee has gone very completely into all the possible sources of alcohol in that continent and concludes that while potatoes would be too expensive, large crops of Sorghum (S. saccharatum) could probably be grown yielding 100 to 180 gallons per acre, while Cassava, which gives a higher yield, might be equally suitable. Synthetic alcohol is possible, and one process is being worked successfully by a Swiss hydro-electric company, which is able to sell pure spirit at 1s. 8d. per imperial gallon.

On the Continent the price of the spirit compares favorably with coal, gas and oil, so that it is used for domestic purposes in addition to its use in various industrial operations. For power purposes a special engine is required if the best results are to be obtained, though petrol engines can be adopted on alcohol as was demonstrated in Germany early in the war, when the Russians had overrun Galicia and a shortage of petrol was threatening disaster to the German transport service. With petrol at 40.5d. per gallon and alcohol at 30d., the cost per horse power hour is the same using the same engine, and assuming that with petrol it has a thermal efficiency of 20 per cent., while when altered for alcohol it has an efficiency of 22.5 per cent. Specially-designed alcohol engines will give 30 per cent. or more with a corresponding decrease in fuel cost. The increased thermal efficiency is due to the increased compressions (as high as 180 to 200 pounds per square inch) which can be employed without danger of pre-ignition. With petrol, 80 pounds per square inch is about the limit. After the war petrol will hardly go below 2s. per gallon, which is about the pre-war cost of alcohol, but it is quite clear that alcohol could be sold at a much lower price than this if the industry was handled sympathetically and not overburdened by excise restrictions. The advantage of alcohol as a fuel as compared with petrol are: (a) smoother running; (b) absence of carbonization; (c) absence of unpleasant exhaust; (d) greater safety from fire owing to its miscibility with water. On the other hand it is not suitable for high-speed engines, and will not start from the cold, so that either an auxillary petrol tank and carburetor are required, or some heating device must be used. During the transition stage from petrol to alcohol it may be desirable to overcome the difficulty by mixing alcohol with some other liquid fuel such as benzine or sulphuric ether. This would both overcome the difficulty in starting from the cold and also enable existing engines to be used without alteration.

SEAY REFRIGERATION SYSTEM

In describing the Seay ammonia absorption refrigerating plant to the Liverpool Engineering Society, Mr. B. Rathmell said that it had been proved capable of making 25 tons of ice per ton of coal burned, with an estimated evaporation of 9 lb. of steam per pound of coal. In this system of refrigeration the absorbing medium used is ammonium nitrate, normally a crystalline salt. In absorbing ammonia it changes into a sticky viscous liquid form. It is stated that 3 lbs. of this salt absorbs 1 lb. of pure ammonia. Thus, in the absorber the salt takes up ammonia gas, as it comes from a refrigerator or ice-making tank at low pressure and temperature, the crystalline salt changing into thick liquid form. In the generator this liquid is heated by steam coils until the ammonia is driven off again into an ammonia condenser of any ordinary type: the salt reverting to its solid form in the process. In connection with the generator it is claimed that much economy in heating is obtainable over what can be secured in the older water and ammonia absorption plant. This is because the change of state of the salt from liquid to solid form liberates its latent heat of liquefaction, which goes towards the heat required for vaporizing the ammonia; and thus of the, approximately, 520 b.t.u.'s required to vaporize each pound of ammonia only about 200 b.t.u.'s have to be provided by the steam heating coils.—The Engineer.

ADMISSION OF AIR

To guard against the escape, unburned, of carbon monoxide gas, and of the tarry matters that are distilled off from the coal it is desirable to admit an extra supply of air, just after fresh coal has been thrown into the furnace, and also when the fires are thicker than usual. For this purpose the fire doors are usually provided with draft registers, and these should be well regulated at all times. The amount of air that enters the furnace in this way is not sufficient to take care of any considerable quantity of freshly-fired coal, however, and it is therefore desirable to keep the fire doors themselves open by a small amount while the first part of the fresh coal is burning off, unless the furnace is designed so that the requisite air can be introduced in some better way. It is usually sufficient to "crack" the doors, as the firemen call it,—that is, to leave them open by a crack. Care should be taken to avoid the admission of too great a quantity of air in this way. When the fire doors are left open to any great extent and for any considerable time, there is danger of the boiler becoming locally chilled sufficiently to start cracks or checks in it, this action being especially notable along the first girth joint of a horizontal tubular boiler, back of the fire door. Having these facts in mind, the fireman should be careful not to "crack" the doors too far, nor to leave them wide open any longer than may be necessary, when he is firing.

It is not scientifically correct to admit cold air through the fire doors, but they are very generally used for this purpose, because in most of the boiler plants of the United States no other means of admission is provided. It would be best for the air to enter the furnace through the fuel-bed, under all circumstances; but as there are times when a sufficient amount cannot be had in this way, it is necessary to consider what mode of admission is most advisable for the supplementary supply. Of the various methods that have been tried or proposed, admission at the bridge wall is by far the best, when the setting is properly designed with this in view. The bridge wall should be hollow, with a space, about half as wide as the length of a fire-brick, running through it from one side of the furnace to the other. Fire-bricks should be laid over this space to form the top of the bridge wall, the bricks being set on edge, with their lengths parallel to the length of the furnace; a clear interval about one-quarter of an inch wide being left between each brick and its neighbors, for the exit of the air. Ducts through the brickwork of the setting convey the air to the bridge wall, and dampers are placed in these ducts so that the supply can be regulated at will. Cleaning doors are also provided, for removing the fine dust that accumulates in the air passages. Air admitted in this way cannot chill the boiler, and it is much more effective in promoting combustion than it would be if admitted through the fire doors.

SOME BOILER TROUBLES, THEIR ORIGIN, PREVENTION AND REMEDY

(Continued from page 186)

grains sulphate, the remainder being silica, iron, etc.

The treatment required is as follows: 6 grains carbonate require 1½ ozs. caustic per 1,000 gallons.

$6 \times 1\frac{1}{2} \times 4 = 36$ ozs. caustic.

This will also precipitate 8.16 grains sulphate:

16.32 — 8.16 = 8.16 grains sulphate remaining

$8.16 \times 1.75 \times 4 = 57.12$ ozs. carbonate

That is, 36 ozs. of caustic soda + 57.12 ozs. carbonate of soda, will precipitate the solid matter.

The repair of a bulged or bagged plate will depend on the extent of the injury. Usually it will require the injured part to be cut out and a patch fitted. In some cases if the injury is not severe the boiler can be continued in service with a slight reduction of pressure. Sometimes the plate can be warmed and jacked up into place. This latter method should be done only when the bulge is very slight. When the bulge is deep, but of small diameter, the piece can be cut out and an oval patch fitted on the inside of the boiler. This will necessitate removing some tubes, but this is inevitable. The patch should always be fitted on the inside of the shell, otherwise a pocket is formed for the trapping of more scale and a repetition of the trouble. The rivets on the fire side should be finished off with fairly flat heads, the holes being countersunk. This will save the rivet heads from being burnt by the fire. If the patch needed is very large, one thing should be carefully guarded against; this is, the tendency of boilermakers to fit a square patch with single rivets. If a square patch must be used it should have its longitudinal seams of the same or nearly the same percentage of strength as the other longitudinal seams in the boiler. After the patch is made, the working pressure of the boiler should, strictly speaking, be calculated on the percentage of strength of the weakest point. I have seen a boiler with an 84 per cent. longitudinal joint repaired with a patch, the longitudinal seam of which was 56 per cent. The most satisfactory patch is the elliptical one, by means of which the original strength of the joint can be retained while using only one row of rivets. This is because the seam lies between a circumferential and longitudinal seam, really being a helical seam. If the bulge is say, not more than an inch deep at its extreme depth, and of fairly even proportions, in which case one can be reasonably sure that the metal has not been drawn to any great extent, a reduction of pressure can be made and the boiler allowed to run. The reduction of pressure will be ascertained by calculating the boiler as being of a diameter equal to the original diameter plus twice the depth of bulge, and making a deduction in the thickness of plate. It is a matter of judgment for an experienced man.

In the case of firebox boilers overheating is more likely to result in cracks than bulges, owing to the staybolts holding the plate up. If a good man is available with an electric welding outfit, repairs can be well and cheaply made, otherwise a patch is necessary, and soft patches can be applied temporarily. In Scotch marine boilers the danger is a collapsed furnace tube or combustion chamber crown. The furnace, if not very badly collapsed, can be jacked up and the combustion chamber crown can be drawn up if not too far gone.

The electric welding apparatus in the hands of a skilful operator is a great help in boiler repairs. Cracked tube plates, leaky seams, wasted plates, burnt door dogs, all can be repaired or built up by this process. Staybolt ends that have been burnt off can be rebuilt in place and cracked furnaces repaired. It has saved many boilers from expensive repairs or being scrapped, and is perfectly reliable if used by a skilful operator.

This article has attempted to point out some of the more frequent causes of trouble, where to locate and how to prevent and remedy them. It may be a help to many engineers in Ontario who now have the privilege of acting as boiler inspectors. It does not profess to touch on everything pertaining to the subject, and in fact only mentions the types of boilers in general use in Canada.

To do more would be impossible in the space available. What has been done the writer hopes will be of interest and use to boiler operators.

GAS FIRING FOR BOILERS

By M. M.

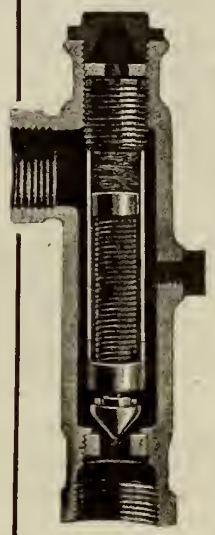
It has for a long time been levelled against electrical engineers that in their use of fuel for generating purposes they waste the whole of the by-products. This question has now, on account of the present-day necessity for conserving all our resources, become of great importance. The most careful conservation is especially desirable when dealing with coal, since the by-products which would be obtained were another system of combustion adopted, include a large number of chemicals that are either very scarce or very urgently needed. Among the former are dyes and chemicals, such as drugs and photographic developers, while among the latter are substances essential for the manufacture of explosives. It appears to be agreed by all generating engineers that the gas-engine is no longer an alternative for the operation of large dynamos; modern practise in power supply points to the use of steam turbo-alternators up to 50,000 or even 100,000 kw.

Hitherto gas firing has not quite achieved financial success. This is fortunately not due to any inherent defect in the system itself. Being a new process this method of using the coal is merely at an early stage of its development, and has not, for this reason, evoked sufficient confidence to be adopted to any extent in practise. When the crit-

Save Power

It costs money to generate steam. Don't waste steam. The

STEAM TRAP SARCO



can be used anywhere in a line and for any given pressure from 0 to 200 lbs. It is cheap because it is made on the right principle. A bucket or float trap costs more because it has to store water to operate it and is therefore big and cumbersome. A return trap also has to have storage capacity and it usurps poorly the functions of a steam pump. It is not more efficiency you pay cash for, but weight and complications.

Worse still, when you conduct steam lines long distances to a big trap, you waste steam constantly in your returns.

Put a Steam Trap SARCO on every machine and at every point that needs trapping and have nothing but condensation in the return. That means efficiency; that means steam saved. Remember, the SARCO is made in all sizes from ⅜ in. to 3 in. and is as efficient for high pressure as for low.

Write for our free trial offer and become convinced.

Canada, Peacock Brothers, Montreal.

ical point has been reached at which a novelty is made at least as economically as existing methods, improvement is accustomed to take place rapidly. In the case of gas firing, there are two causes which are at present keeping its efficiency down. The first of these is due to the boiler itself, which, as everyone knows, is an old piece of apparatus being now used in a new way. All its dimensions and its design generally have been decided upon and standardized for the old set of conditions. For example, the diameter and length have been fixed after long experience as the best for coal firing. The circulation of water inside the boiler, which is satisfactory under present circumstances, is interfered with when the intense local heat of the furnace is replaced by a more distributed system. All these points will have to be considered before the full benefit is derived from the new method of firing. The second cause is the need of experiment with regard to the conditions under which the gas flame is produced. This is quite a new problem, and many different arrangements will have to be tried and modified before the best design is arrived at. When this is the case it will, in all probability, be found that a new era has begun for the production of electricity, and a great step has been made in the direction of national economy.

In addition to the advantages given below, the way will be thrown open to the utilization of waste products which are unfitted for direct combustion in the firebox. There seems to be no reason why such waste materials as small timber should not be gasified and their calorific value made use of in power production.

JOHNS-MANVILLE DENVER OFFICE FINDS LARGER QUARTERS

One of the chief characteristics of the Johns-Manville organization is the unfailing tendency to develop and expand.

During the last few years the managers of the Johns-Manville branch offices in Chicago, Minneapolis, Louisville, Indianapolis, DesMoines and Omaha, have all found it necessary to find new quarters and larger offices to take care of the increased volume of business which they have built up.

The latest Johns-Manville manager compelled to seek larger office quarters to take care of past and future growth, is Louis H. Inglee, of the Denver office.

On April 15 Mr. Inglee moved from the Denver Gas and Electric building, into splendid new quarters in one of Denver's most desirable business sections, the Iron building, 1021 17th St.

Mr. Inglee will continue to be supported by an efficient sales force, trained in the best traditions of Johns-Manville service and satisfaction.

CATALOGUES

The General Industrial Catalogue of TYCOS Instruments containing 422 pages of useful and interesting temperature information is now ready for distribution. This new publication describes the whole line of TYCOS instruments for the indicating, recording and control of temperature. Many special applications are illustrated, showing the manner in which TYCOS instruments can be adapted to diverse temperature needs. Practically every instrument manufactured by the Taylor Instrument Companies for industrial purposes is illustrated and much explanatory matter descriptive of their construction and principles of operation is given. The list includes thermometers of every description, index and recording thermometers. hydrometers, pyrometers, temperature and pressure regulators, barometers, absolute pressure and draft gauges. It is a handsome publication, well bound, printed on paper of excellent quality.

The Link-Belt Company, Chicago, Ill., have issued a bulletin number 220, descriptive of the Peck Over-lapping Pivoted Pocket Carrier for the economical and efficient carrying of coal, coke, ashes, cement, sand, ore, stone, and other materials.

Engberg's Electric and Mechanical Works, St. Joseph, Mich., have issued a catalogue descriptive of the Engberg direct current generating set, which is made in capacities of from one to fifty kw. This publication is an excellent example of commercial printing and furnishes an unusually complete description of the generating set manufactured by this firm.

Get The Most Out Of It

"In every business club you will usually find two classes of members, those who get nothing out of their membership and those who find it the best investment they ever made." (Class).

But the man who gets nothing out usually puts nothing in but his application and fee.

Are you getting all you can out of your investment in POWER HOUSE?

Here's an engineer who is: **"I consider POWER HOUSE the best paper in Canada, as it touches on local power plant equipment and problems as no other paper does for the engineers."**

Another engineer writes that by studying the editorial pages he gets great help and by reading the advertising pages he learns all about the latest equipment. He says: "The circulars about new equipment usually are kept in the offices, but POWER HOUSE reaches the engineer straight."

Get the most out of Power House by reading it from cover to cover.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G. MACDIARMID,
Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D.,
Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

GREEN'S ECONOMISERS

and

Hi-Speed Radial Flow Fans *Hi-Efficiency*

For Forced and Induced Draft Service

One of the unusual features of our RR type Radial Flow Fans is the special design of the blades which enables them to run clean under the hardest conditions of induced draft service.

Our engineers are always glad to co-operate with you in designing your power plant or boiler house.

Diagram No. 1

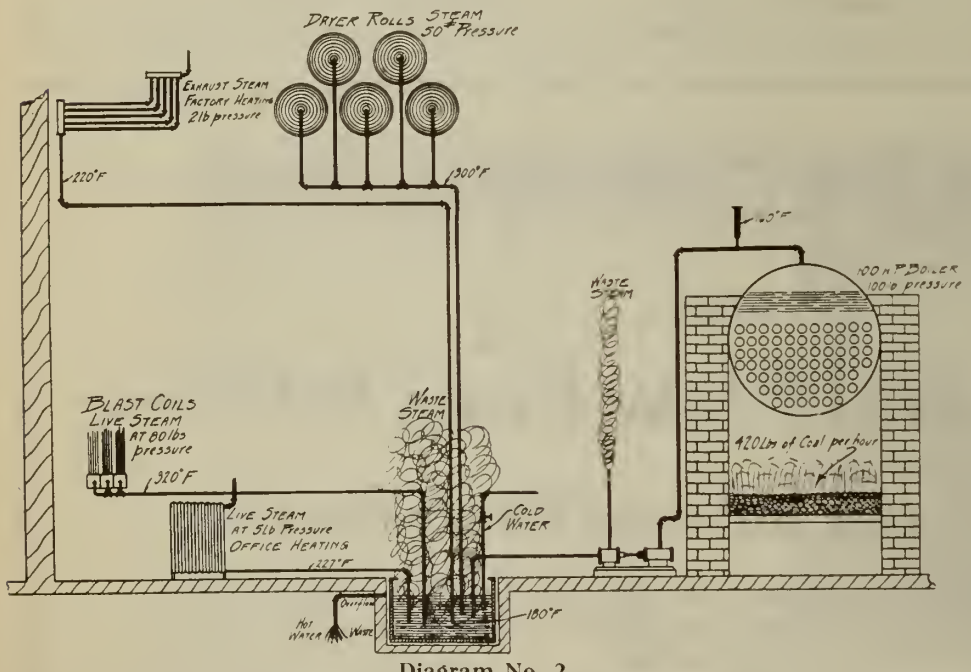

Diagram No. 2

Do you want any information on the subject of CONDENSATION HANDLING IN RELATION TO FUEL ECONOMY? Do you want to make your plant MORE EFFICIENT? Do you want to Cut expenses in your Steam plant? SAVE FUEL?

If you Want INFORMATION, write for our Bulletins. You will find them interesting.

You will get Catalogues later (IF YOU WANT THEM) not otherwise.

Every Steam line condenses SOME part of Steam which it conveys.

Every square foot of heating surface condenses MORE Steam.

Steam to be efficient in Service must be DRY and HOT. Wet Steam is NOT Hot Steam. It can't do the work you want.

"Live" Steam is EFFICIENT. "Dead" Steam is NOT.

YOU KNOW THIS—You're on to your job—You Cover your Steam lines—You Dry your Steam—You Drain your lines—You Induce Circulation. O.K. THAT'S FINE. BUT What do you do with the Condensation or water which you take out of the lines and heating surfaces?

Do you treat it. as of "No further Use"? Throw it away? Like *Diagram No. 1.*

Do you drain it into a "so-called" Hot well? Cool it down so the Pump will handle it? Like *Diagram No. 2.*

Do you do better? Pass it through an "alleged" Water Heater. Cool it down again. Draw live steam from the boilers to pump the COOLED condensation (or water) into the HOT Boilers. using two Pumps to do it. Like *Diagram No. 3.*

Just mention what you are interested in.

"Boiler Feed Problems."
"Low Pressure Heating."
"High Pressure Heating."
"Drying"—"Cooking"
"Line Drainage."
"Water Heating."
"Faulty Circulation."

2002-4 Dundas Street West, Toronto

GEO. W. COLE, Limited

System Saves Your Fuel

ILLUSTRATED HERE ?

OR, do you drain the water from the lines and heating surfaces, and dump it straight where it belongs? Under its own power, there to make more steam. HOT WATER INTO HOT BOILERS. Like *Diagram No. 4.*

The average feed water heater temperatures range between 180 and 200° F., or, 12 to 32° BELOW ATMOSPHERIC BOILING POINT. YOU KNOW THIS.

Water drained from steam lines, and heating surfaces may be as hot as 220° to 350° in ordinary steam plants, depending on the pressure.

ANYWHERE FROM 8 to 108° ABOVE BOILING POINT AT ATMOSPHERIC PRESSURE.

YOU KNOW THIS ALSO.

NOW, CAN YOU HEAT YOUR RETURN WATER UNDER THESE CONDITIONS? OR, DO YOU COOL THE CONDENSATE DOWN?

Condensation is HOT WATER (H-O-T) 220 to 350 degrees temperature. HOT Water saves FUEL. YOU KNOW THIS. WE WON'T ARGUE THIS STATEMENT.

If your Return lines are handled like sketch No. 4, we can't help you any, in handling condensation. BUT, if your Return lines are handled in any other way, we CAN help you.

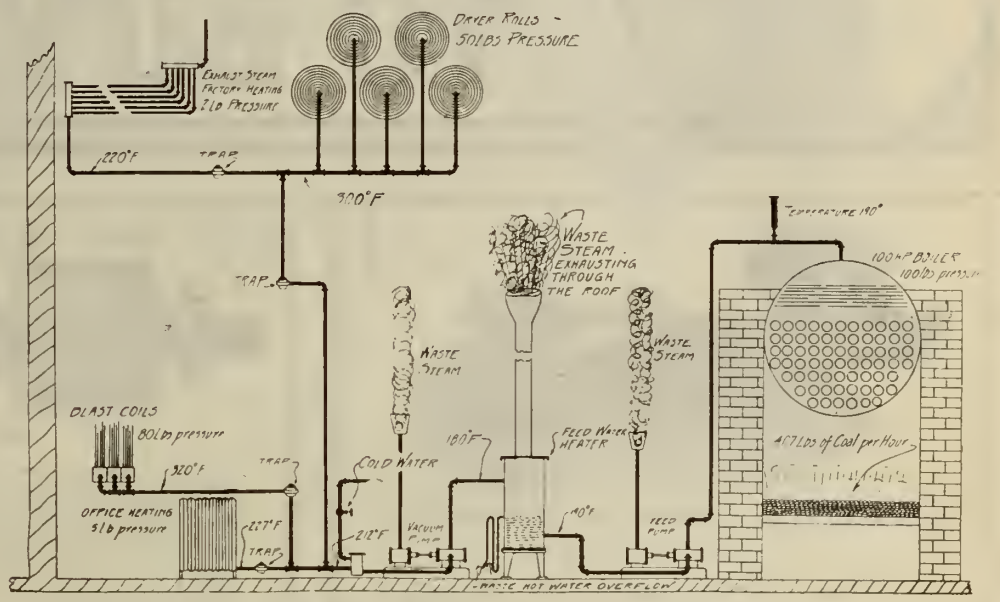

Diagram No. 3

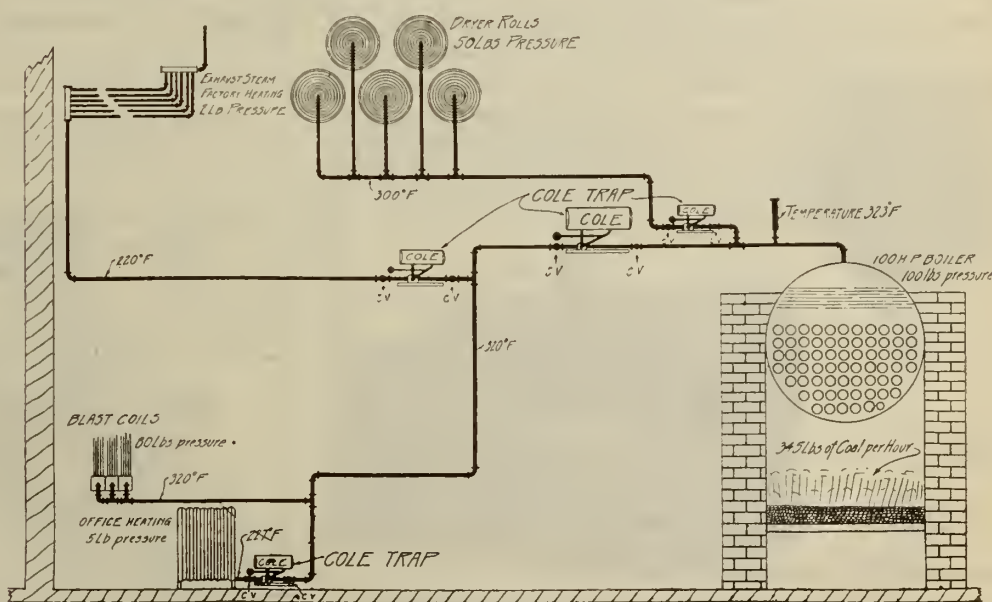

Diagram No. 4

This is the "COLE" Return Trap

In a class by itself. OK'ed by the Provincial Boiler Inspection Department.

BUILT FOR STRENGTH AND SERVICE

Examine the Grates in the four diagrams and estimate how much Fuel the "COLE" Return Trap will *save you.*

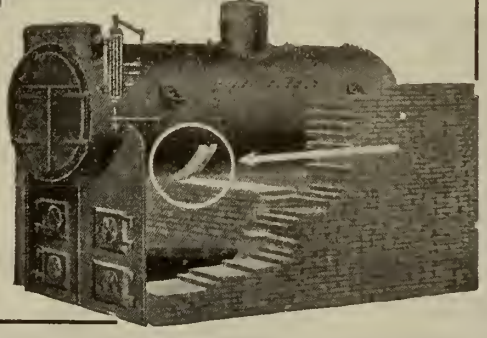
NATIONAL Boiler Girth Seam Protector

Protection means longer life and greater efficiency

If your Boiler is not Fire-cracked it eventually will be. Prevent this by putting on a National Boiler Protector. You will save cost in repairs and prolong life of the boiler. All new boilers should be protected. If your girth seam is giving you trouble at the present time, have the seam caulked up, attach one of these protectors and the seam will remain absolutely dry thereafter.



Guaranteed for one year. We make protectors for patches and all styles of boilers. For full particulars, write—

Will Bolshevism Spread to Canada?

WILL the Russian reign of terror spread to Canada? Bolshevism is the most disturbing element in history and it is coming westward—will it reach us? Here is an article which will interest you—and your customers—

"The Menace in the South"

BY AGNES C. LAUT

IN JUNE

MACLEAN'S

"CANADA'S NATIONAL MAGAZINE"

Bolshevism is rampant in Mexico. The danger is grave that it will spread north to the United States and Canada. Miss Laut has just returned from an investigation in Mexico; she writes a sensational article on the conditions there and the dangers from our standpoint in the June MACLEAN'S. Read it—tell your customers about it.

Other Important Features

Canadians will be glad to know that MACLEAN'S is to publish another series of Robert W. Service poems. The first instalment will appear in June MACLEAN'S.

"Victory Stuff" - - - - - **By Robert W. Service**
A powerful poem on the attitude of the returned soldier.

"The Wings of the Morning" - - - - **By John A. Steuart**
A touching war story laid in Scotland. A wonderful story from every point of view.

"The Gold Wolf" - - - - - - **By W. A. Fraser**
The third in the popular series of Bulldog Carney stories and one of the strongest pieces of fiction that MacLean's has ever presented.

"Solving the Problem of the Arctic" - **By Vilhjalmur Stefansson**
The third instalment of Mr. Stefansson's remarkable narrative of his explorations for the Canadian Government.

"The Undercurrents" - - - - - **By J. K. Munro**
An article on the situation at Ottawa, containing all the inside gossip of the capital and a forecast of what is ahead.

June MacLean's—A Big Seller

MACLEAN'S is "going strong." Many prominent Canadians say it is the best general monthly magazine to be found in Canada to-day. Its circulation is growing rapidly. Keep it well to the front—it will pay you. Order sufficient copies to meet the demand.

If your wholesaler can't supply you, write direct to Circulation Manager, C. W. Buchanan, 143-153 University Ave., Toronto.

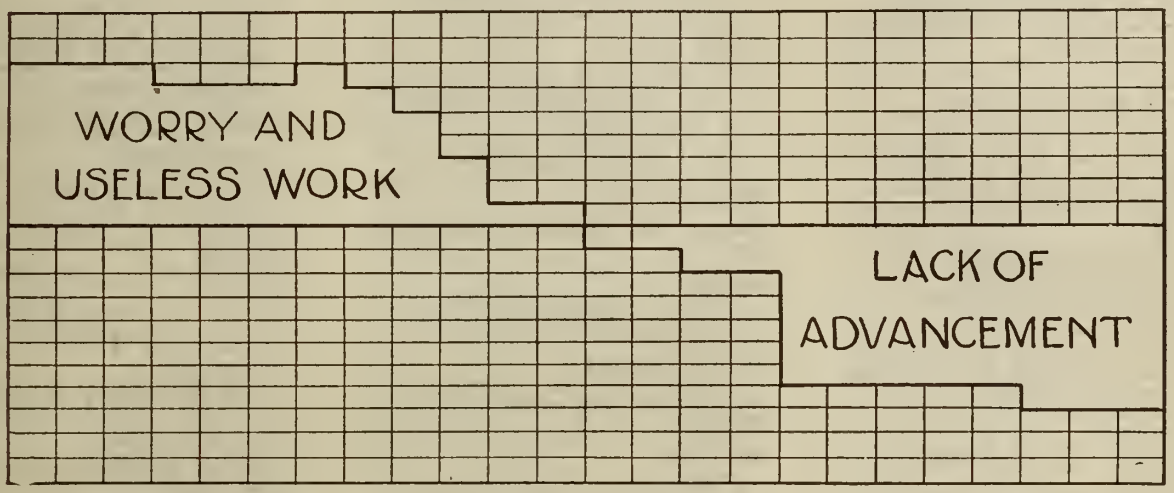
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

Keep the Heat Where It Belongs

PLIBRICO keeps the heat in the furnace, because it forms a jointless one-piece lining in your front door arches, entire fronts, side walls, arches, bridge walls, etc. This lining is gas and airtight, saves fuel while at the same time greatly reduces your furnace upkeep, will last longer, give better satisfaction and can be more easily repaired than a lining constructed of fire brick and fire clay.

Write for free copy of 36-page book of useful information on furnace building & maintenance

Are You An Engineer?

One of the most prominent Engineering Authorities once wrote: "A very important part of an Engineer's training is to know:

WHERE to Find
WHAT He Wants
WHEN He Wants It."

Do *YOU* know *WHERE* to get *WHAT* you want?

Do *YOU* know that *"WILLIAMS"* have *IN STOCK STEAM ENGINES, ALL SIZES*, 1 to 1000 horse power?

Do *YOU* know that "Williams" have *IN STOCK STEAM BOILERS, ALL SIZES*, 10 to 450 horse power?

Do *YOU* know that "Williams" have *IN STOCK STEAM PUMPS, ALL SIZES*, 1 to 1000 gallons per min.?

Do *YOU* know that "Williams" have *IN STOCK AIR COMPRESSORS, ALL SIZES*, 5 to 2000 cu. ft. per min.?

Do *YOU* know that "Williams" have *IN STOCK MOTORS AND GENERATORS*, 1/4 h.p. to 200 h.p.?

Do *YOU* know that "Williams" have *"IN STOCK" A SERVICE DEPARTMENT* giving competent, unbiased engineering advice?

Do *YOU* know that "Williams" have *"IN STOCK"* The largest line of *POWER PLANT SUPPLIES* in Canada?

Now we've told you *WHERE* to get it. Won't you tell us *WHAT* you want?

REDUCING VALVE PERFECTION

J.M.T.

JAMES MORRISON TORONTO

It makes no difference how the initial pressure varies, this reducing valve will keep the low pressure constant.

It is the ultimate valve—it does all that a pressure reducing valve could possibly do.

Made in sizes and with reduction ranges to suit every requirement, and sold with the well-known Morrison guarantee.

May we send complete details?

BRISTLING WITH POINTS

TO SAVE POWER AND INCREASE PRODUCTION
ARE

AMERICAN STEEL SPLIT PULLEYS

Twenty years ago steel belt pulleys appeared for the first time. To-day the steel pulley business on th.s side of the Atlantic alone has grown to an annual output of not less than 500,000 pulleys.

In steel pulleys the American just bristles with points of superiority.

Note the flat "A" Braced Arms (edge on) cut the air and save enormously in power.

Arms not riveted through pulley face, but riveted to interned strengthening rim flanges.

A rim made like a channel iron, central flanges and safety beaded edges.

Ends of arms are all milled to exact length.

Features incorporated in the American. Features that make for longevity, less belt slip. No pulley will resist shocks like the steel.

An American Steel Split Pulley is made from 40 to 60 per cent. lighter than a cast iron pulley designed for equal service.

We have one of the largest stocks of steel split pulleys in Canada and they are the AMERICAN.

This to you, the production superintendent, means the opportunity of getting maximum pulley efficiency.

A Little Letter to the Plant Engineers of Canada

Gentlemen: The following are two extracts from an article which appeared in "Power," under date April 30th, 1918, and the Editor of that Journal has informed me that he would be very glad if I could make use of same for the purpose of Educational Propaganda among Engineers.

"Well, I suppose pumps are necessary about a steam "plant, but I wish that someone would get up something "that would work without valves and pistons in handling "hot water returns. Then there would be less gloom, for "me at least. A pump is a nuisance anyway" (said this Engineer).

"Why, Williams, you don't mean to say that you don't "know of a way to get your returns back into the boiler "without a pump, do you? Didn't you ever hear of the "return loop? No? Well, I ain't got the time to tell "you about it just now, as I have got to get home so as to "keep peace in the family, but the next time I get a chance, "I'll drop in and give you a few pointers on the loop that "may come in "handy some time "or other."

The "STEAM LOOP"---Present-day method

Imagine a Steam Engineer in Canada making the first statement. Is it possible that any Engineer who reads POWER HOUSE *doesn't know about the Direct Return Trap? If so, it is not our fault.*

The writer doesn't know if Williams' friend ever returned to tell him more about the return loop, but he purposes telling you Engineers all he knows about the subject through these ads.

We have endeavoured to place the merits of the Return Trap before Engineers in many ways, and from many aspects.

We are now running a series of ads. in this Journal, which we hope will demonstrate more clearly than ever why a Return Trap should be in your plant. See May 20 issue.

Will you do the writer a favour? Criticize the diagrams, illustrating the ads. Analyze the statements made, and if you have any fault to find, write us a letter, and tell us where we are wrong.

The ads are written for your benefit, and, we believe, have an educational value, dealing as they do with details which are very often overlooked and cause serious loss of plant efficiency.

The writer has taken a chance on Steam Engineers of Canada being open to conviction, and willing to be shown. He has written these ads. for this purpose, and all he asks in return, is, Read the ads. and criticize them, and he has no doubt, it will result in a great many plants being made more efficient by the men in charge of them.

WM. H. ROSE, Engineer.

BOILERS

The recent additions to our boiler shops, with the installation of new and most modern machinery, have placed us in a better position than ever to take care of your boiler and steel plate work.

With a Waterous boiler installed in the Waterous way you may be sure of getting the full steam value from your fuel—whether it be wood, coal, sawdust or shavings or combinations of these. We will furnish you with a setting that is designed and dimensioned to best suit your individual needs.

Some Recent Installations

Our System of Testing Insures Uniformity and Dependability in Dominion Rubber System Belting

Probably the elements that create the most satisfaction in the use of any article are an accurate knowledge of what it will do before it is made and to prove that it will efficiently accomplish its purpose after it is made.

It is on this basis that we build our belting and the knowledge of what it will do is the result of over fifty years experience and research.

We prove by careful tests that every ounce of material is up to our high standard—each individual operation is checked as the belt proceeds from one machine to the next and a sample of the finished belt is tested, both chemically and physically, to prove that it will efficiently serve the purpose for which it was made and that it has a reserve of strength for emergencies.

We want you to test not only our claims of superiority for Dominion Rubber System belting, but our free belting service, in charge of belting experts, who can help to cut your manufacturing costs, by making your equipment more efficient.

A phone, wire or letter to our nearest service branch will enable you to test this service without obligation.

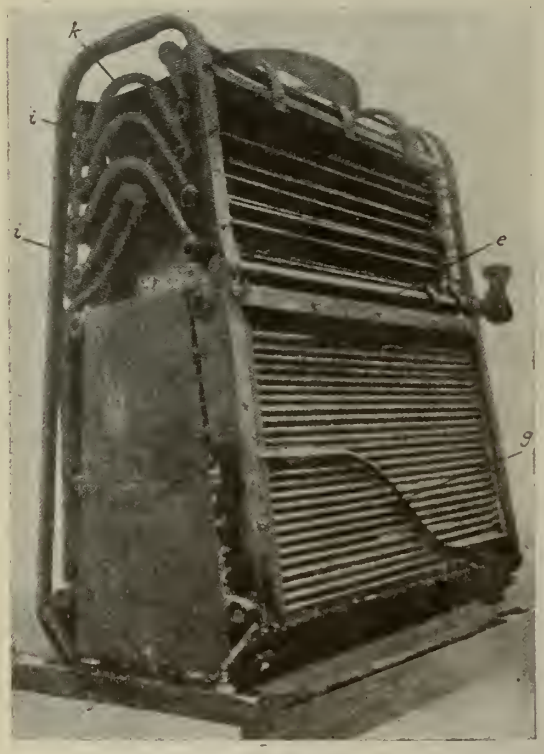
TALBOT

Contra-Flow Steam Boilers

(Equipped with Crude Oil Burners)



Head of Boiler Casing Removed

Cost of Operation is Cheaper Than Any Known Power Producer

Requires one-seventh the space of the ordinary boiler. No brickwork is necessary.

Responds instantly to sudden demands for steam through the automatic control of feed water and fuel.

Water enters the "Talbot" near the stack and leaves in the form of steam near the furnace.

The circulation is through water tubes and is forced at a high velocity by means of a pump doing away with a water drum. By preventing gravity circulation the steam is drawn directly from the lower tubes, eliminating the steam drum.

Two 1,000 H.P. Boilers in stock for quick delivery.

There's a Big Waste in Little Leaks

Do you know that a one-tenth inch pipe-joint leak at 150 lbs. pressure will waste steam in a year at a cost to-day of approximately $825? Figure it out for yourself. Leak one-tenth inch; pressure 150 lbs.; 9 lbs. steam per lb. coal; coal $5.50 ton; 10 hours per day; 300 days per year.
And it's such an unpatriotic waste in these days of coal conservation—such a needless and careless waste at any time—for the leak can be stopped in a few minutes' time with a

YARWAY
PIPE-JOINT CLAMP
Formerly the SIMPLEX

More than 13,000 leaks have been stopped since this effective clamp was first placed on the market. Millions of dollars have been saved. The saving in coal can only be guessed.
The Yarway (formerly the Simplex) can be attached in a few minutes by any workman. The principle can be seen from the illustration shown here.
If there is a pipe-joint leak in any of your lines, tell us the size and we will send you a Yarway for 30 days' trial. Instead of returning it, you will probably be as enthusiastic over its success as the man who said of a Yarway Clamp, "It's worth its weight in gold."

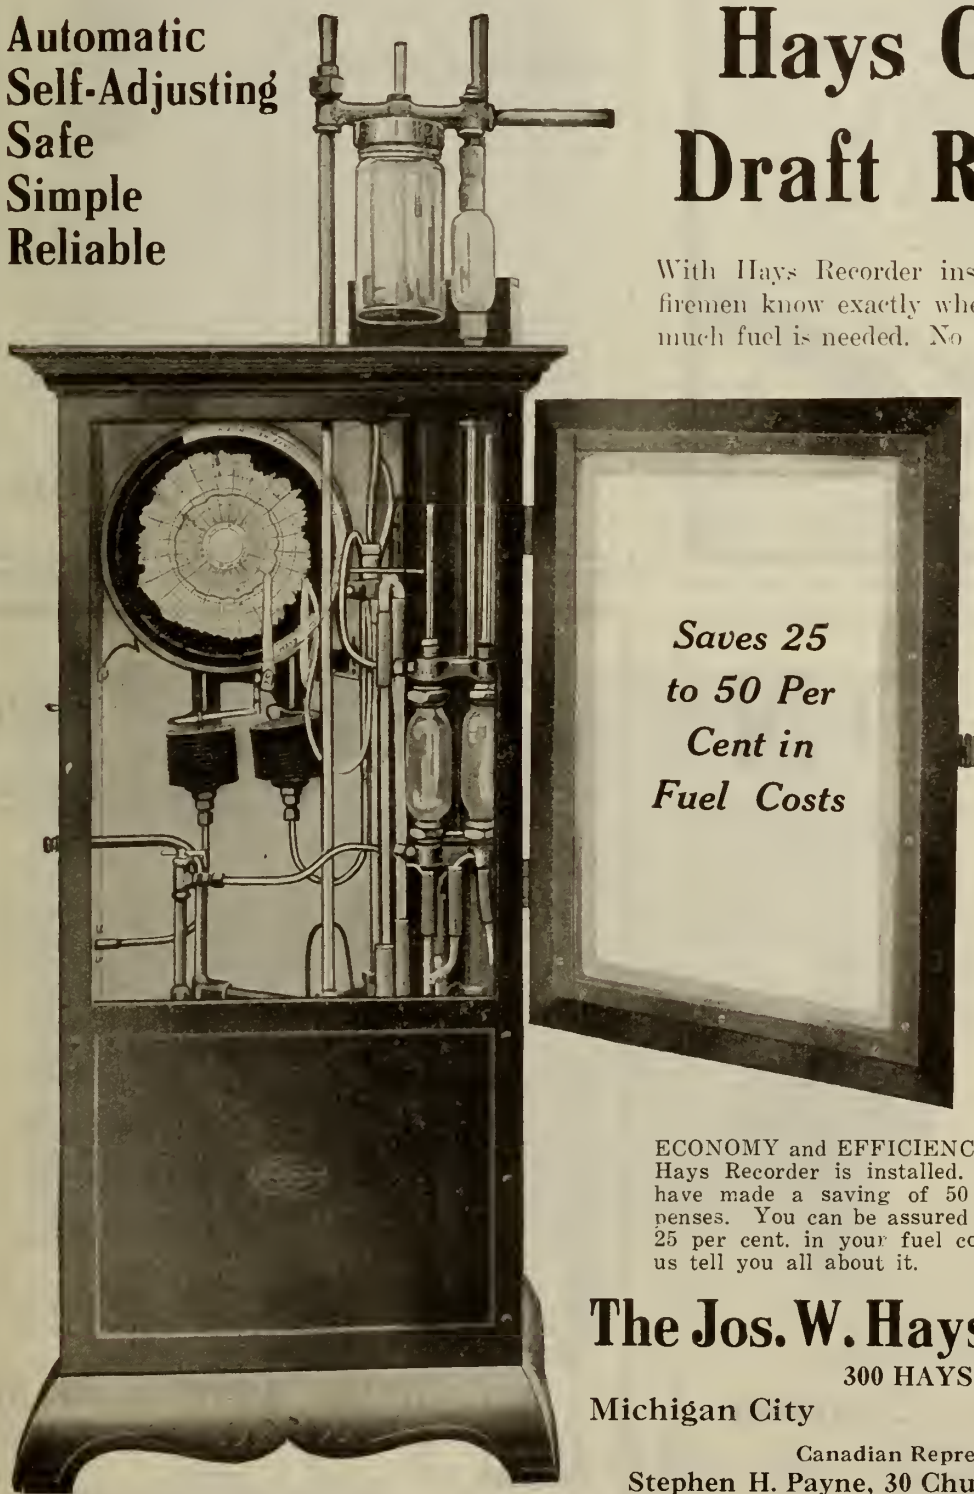
Reliable



Hays CO_2 and Draft Recorder

With Hays Recorder installed in your plant the firemen know exactly when to fire-up and just how much fuel is needed. No waste in time; no waste in fuel. If you are consuming more fuel than is necessary the Hays Recorder will tell you about it. It will expose the cause of the waste and you will easily see how it can be avoided. It points out errors in firing, errors in draft and boiler settings.

Saves 25 to 50 Per Cent in Fuel Costs

The Hays Recorder is automatic, self-adjusting and never fails. It does not depend on hand adjustment and mechanical action for accurate operation. Indications are controlled by rising and falling columns of mercury, water and caustic potash.

ECONOMY and EFFICIENCY follows wherever the Hays Recorder is installed. Some plants using it have made a saving of 50 per cent. in fuel expenses. You can be assured of a saving of at least 25 per cent. in your fuel costs. Investigate! Let us tell you all about it.

When Buying Thermometers

There's Just Three Things to Remember—

First, you must have accuracy and sensitiveness—

Second, durability is absolutely essential—

Third, the thermometer must be suitably constructed for the intended application.

Accuracy, sensitiveness and durability are absolutely guaranteed in

"Crescent" Thermometers

And with nearly seventy years of experience to our credit, we are qualified to properly interpret your needs.

Our Catalog P.H. 200 illustrates and describes "Crescent" Thermometers for every application. Also test thermometers, glass thermometers, etc.

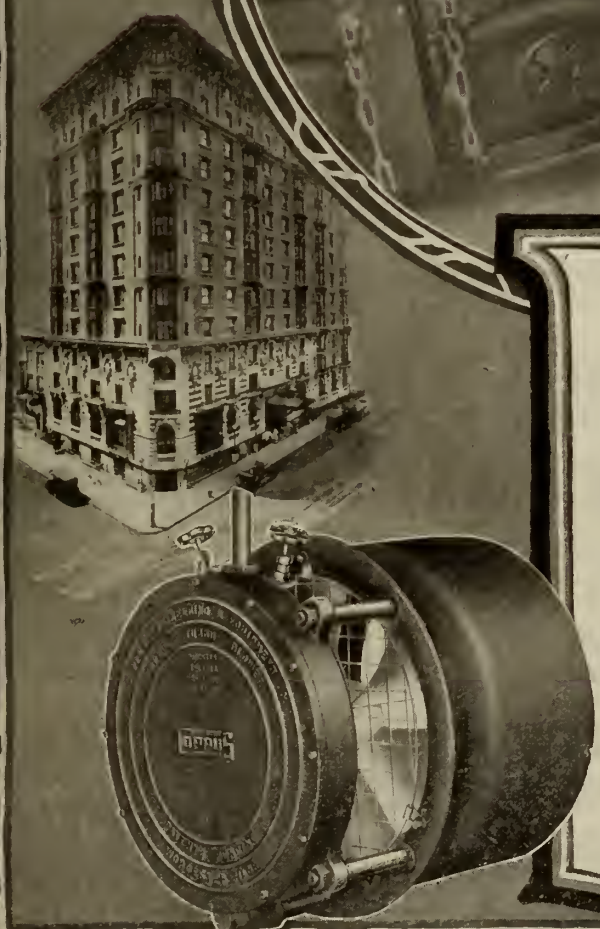
REGISTERED COPPUS U.S.PAT.OFFICE

In Hotels



This is one of the two 18" COPPUS Blowers which have been saving money in the power plant of the Hotel Seville, New York City, for more than two years. They cut coal costs, meet peak loads quickly, keep steam pressure constant, save firemen's labor, prevent clinkering, get all the heat out of the fuel, and—an important item, run smoothly and quietly without trouble.

That COPPUS Blowers operate as effectively in hotels as in power plants of mines, mills, factories — in power plants of any sort — is emphatically proved by the fact that numerous other prominent New York hotels use blowers bearing our trade-mark. For example, Broadway, Central, Girard, Latham, Marseilles, Martinique, Shelburn, Langham, Theresa, Waldorf Astoria, etc., have satisfactorily demonstrated the money saving possibilities of COPPUS equipment.

What COPPUS Blowers have done in other plants they can do in yours. Allow our engineers to show you how **"COPPUS equipment can save you money."** Write for Blower Catalog H8.

Real Data on Steam Line Insulation

You will find this 84-page book different from most catalogues dealing with pipe coverings. Glittering generalities and broad, unsupported statements have been left out. In their place are given concrete facts, such as:

1. The comparative heat insulating efficiency of Nonpareil High Pressure Covering and other standard brands;
2. The transmission of heat per lineal foot through the various sizes and thicknesses of Nonpareil High Pressure Covering;
3. The loss of heat from bare pipe;
4. A table showing the most economical thickness of Nonpareil High Pressure Covering to use for different service conditions;
5. A chapter on the proper insulation of underground steam lines;
6. Detailed specifications for the proper insulation of steam lines, boilers, etc., based on the cost of steam.

In fact, the book is most complete, covering as it does the whole question of efficient steam line insulation in detail.

Superintendents, engineers, managers and all others interested in the conservation of steam and fuel will find this book of value. It is more than just a trade catalogue, and merits a place in your permanent business library.

SENT ON REQUEST

A copy of the book and a sample of Nonpareil High Pressure Covering will be cheerfully sent on request. If you are interested particularly in insulation for tanks, feed water heaters, evaporators, ovens, etc., ask also for a copy of the booklet, "Nonpareil High Pressure Blocks and Cement" and samples of these materials.

Armstrong Cork & Insulation Co., Ltd., 504 McGill Bldg., Montreal, Que., Can.

Also manufacturers of Nonpareil Insulating Brick for boiler setttings, furnaces, etc.; Nonpareil Cork Covering for drinking water systems; Nonpareil Cork Machinery Isolation for noisy machines, and Linotile for floors in offices, residences, etc.

Nonpareil High Pressure Covering

You Can Learn a Lot from Advertising

The main thing an advertiser wants to do is to tell you plainly just how and why his goods are worthy of your consideration. You can learn a great deal from that alone, because many things you see advertised are the things you buy and use in your regular daily life. By reading the advertisements, you can learn the names and read the descriptions of the things that are best and most satisfactory.

But advertising teaches even more than that. All advertisers try to make their advertisements themselves valuable to you.

A good many people have learned a whole lot about good music, good books, good food, good clothes, ways to keep healthy, ways to live comfortably, ways to keep the house and grounds looking well—they've learned all these things and many other things *just by reading advertisements.*

Read the advertisements right along, and you will learn a great deal that will be helpful and valuable to you as you go through life.

Written by LIFE'S advertising manager. POWER HOUSE *advertisments have proven of great worth to Canadian engineers. Our advertisers recognize this and prepare their messages accordingly. Keep thoroughly up-to-date by studying BOTH editorial and advertising pages.*

If a throttle valve could talk of rod packings

—it would tell of unnecessary steam waste. Not the dribble that leaks from the stuffing-box—this is insignificant. But of that which is wasted in driving an engine when the rod is gripped tightly and its free action hindered by common packings. And it would tell of Sea Rings—how they pack rods leaklessly while relieving them of friction.

Sea Rings aren't solid or inert—but are automatic, pulsating and self-adjusting.

As steam or liquid enters the stuffing box, it fills the hollow space between the "lip" and "heel" of the Sea Ring, and pressure forces the lip against the rod, with just enough pressure to stop leakage. As pressure decreases, the Sea Ring relaxes its grip on the rod.

For the rejuvenation of pump, engine or compressor, Johns-Manville Sea Ring Rod Packing is unequalled. Our nearest branch will tell you how and where to try a set and be convinced. Write them today.

Hamilton Waterworks; Some Features of Design

The High Level Booster Station and the Laying of the Intake Piping Are Described, Together With Some of the Problems Encountered in the Design of a Large City Waterworks System

By F. C. PERKINS

THE accompanying illustration, Fig. 1, shows the High Head electric pumping station at Hamilton, with its 4 centrifugal electrically-operated units, while in Figs. 2, 3 and 4 may be seen the intake crib ready to be launched, the 48-in. intake pipes in 140 ft. lengths; also the 48-in. header and 30-in. valve to the main. The writer is indebted to Andrew F. Macallum, C.E., city engineer of Hamilton, Ont.

He points out the fact that the City of Hamilton, Ont., completed its waterworks system in 1859, which system was developed gradually to meet the growth of the city until 1912, when it was found that the rapid growth of the city necessitated the complete renewal of the entire system. At this time there were in operation four steam pumps, having a combined discharge of 13¼ million gallons (imperial) per 24 hours, and three mains to the city, 18 in., 20 in. and 30 in., respectively. Two of these pumps and the 18 in. main were installed in continuous use since 1859, and these pumps of the vertical walking beam plunger type are today somewhat of a curiosity. These old pumps are yet in commission, but used only in the event of interruption to the electrical-driven turbine pumps installed during the reconstruction, and when the other two and new steam pumps cannot meet the demand.

Hamilton lies at the westerly end of Lake Ontario, where, at its extreme end, a sand ridge cuts off the lake from the Burlington Bay, on the shores of which the city lies. Owing to its location and this sand ridge, through which a short canal is cut to the lake, combined with the fact that most of the sewage from the city is treated at Disposal Works before entering the bay; it has never been found necessary to treat the water taken by the intakes from Lake Ontario. This places this city in the unique position of being about the only city draining water from the lower great lakes that has not treated its water supply. In connection with the original installation, two intakes extended into the lake, one cast iron 20 inches in diameter, for a distance of 1,000 feet, and a wooden box intake, three feet square, a distance of 300 feet, each having its inner end in a settling basin, from which wooden conduits led to the wells at the pumping station.

Engineer Macallum maintains that one of these wooden conduits, placed in 1859, was found to be in first class condition after 55 years' service. It was decided to construct a new intake 4 feet in diameter and 2,100 feet in length, which would bring it to a depth of thirty-two feet of water in the lake. This steel intake pipe including intake piece, sluice valve and expansion joints, cost $20,250, delivered on the site and rivetted in lengths approximately one hundred and forty feet, on the ends of which were flanged pieces. The price mentioned included also the lead gaskets and bolts.

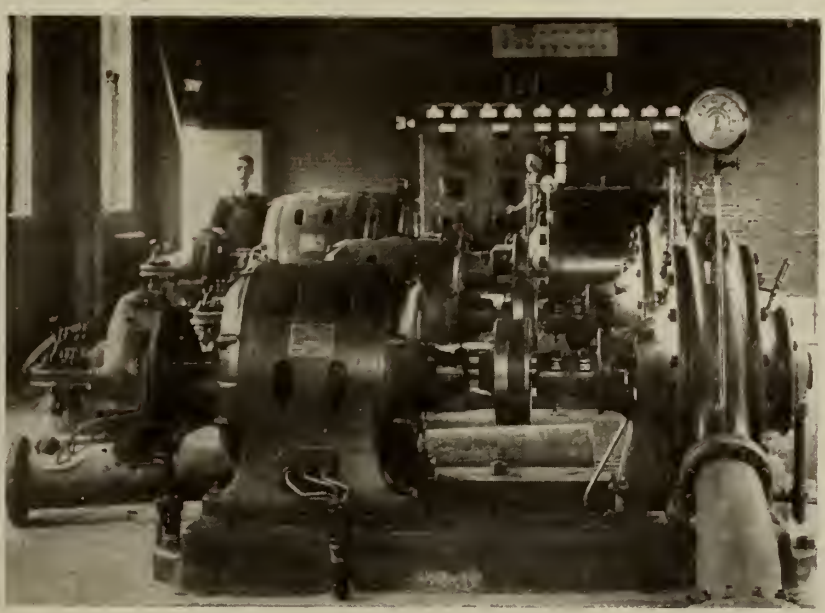

FIG. 1—HIGH HEAD ELECTRIC PUMPING STATION WITH FOUR MOTOR-DRIVEN UNITS.

The accepted tender for laying this pipe was $35,000, which included the building and placing of the intake crib and a concrete valve chamber and house at the settling basin end. As ice ridges formed out in the lake for a distance of about 1,000 feet and in some places thirty feet high, to protect the pipe, it was necessary to lay the pipe in trench on the lake bottom, so that when filled in again the pipe was covered. Concrete in bags was placed around the pipe for 300 feet from the shore line as an added precaution. Four piles were driven in the trench in such a position that when a 140 foot section was floated into position two piles would be at each end of the section. Across the two piles at each end a sill was bolted at grade and the pipe lowered to rest upon these sills and held in position there by wooden blocks on either side. A cap was bolted across the two piles over the pipe after the section had been bolted to the preceding section by the drivers. Besides alignment the object in driving these piles was twofold, first, for ease in joining up two sections clear of the sand; and secondly, to prevent as much as possible divers not bolting up the lower sections of the pipes, because of difficulty of access. As there was practically little possibility of scour on account of the method of construction adapted it was not considered necessary to space the piles closer.

In an examination of the plans for intake cribs adopted by the cities on the Great Lakes, it was found that the minimum size was forty feet square and of sufficient height that the mouth of the intake facing upwards was at least seven feet above the bed of the lake. This

FIG. 2—INTAKE CRIB AT HAMILTON READY TO BE LAUNCHED.

minimum size Engineer Macallum did not consider necessary, but designed the intake crib to be 24 feet square, placing rip rap around the outside, and this has since been found quite satisfactory. No iron was exposed about the intake opening, but these were constructed with oak plank to prevent the prevention of anchor ice. In the gate valve house were placed fish screens for obvious reasons. A reinforced concrete conduit, 4 feet in diameter and 2,000 feet long was constructed to the large well at the pumping station. This conduit before reaching the pump well passed through a screen chamber, through which the old two wooden conduits also passed.

Each of the turbine pumps fed from a small and separate well connected with the main well with a gate valve cut off. By this method any foot valve could be inspected and repaired if necessary without interfering with the water supply to the other pumps. At the inlet and outlet of each conduit was placed a sluice valve, so that any conduit could be cut off, or either part of a conduit. Engineer Macallum points out that in the construction or reconstruction of any waterworks system, the pumping plant is of paramount importance, what power used, steam, gas or electric will depend principally upon the cost of these motive agencies delivered on the shaft. Other considerations will be the capital cost of installation, including size of relative building and cost of operation with depreciation.

In Hamilton on account of the low cost of electric power ($16.50) per annum, it was decided to increase the number of electric driven pumps to meet the future demands and the pumping station for the units already installed was enlarged. Two new electric driven turbine pumps were installed, each of 6½ million Imp. gallons per 24 hours, or of the same capacity as two units already in operation. There is a steam plant also drawing a capacity of 13½ million gallons per 24 hours, which is generally held in reserve, or to carry the peak load during periods of heavy consumption.

Regarding the two stage turbine pumps that the City of Hamilton installed at its main pumping station, pumping to a head of 285 ft. with an efficiency of 75 per cent. under full load, it may be mentioned the tenders for two 6½ million gals. (Imperial) turbine pumps in place varied from 5,500 to 9,800. Extra impellers capable of lifting the water to 300 feet were included and the pumps had to be successfully operated for two weeks before acceptance. Besides the main pumping station there was built a booster station to replace steam and air lift pumps to carry the water to greater elevations than possible with the main pumping station without causing excessive pressure in the lower portion of the city. This station contains four turbine pumps, each of one million Imperial gallons per 24 hours. Two of these pumps raised the water about 80 feet above the level of the reservoir to which the main station pumps delivered the water, and two pumps raised the water 280 feet above this level. Two stage pumps only were necessary for the lower level below the Mountain plateau, but six stage pumps were required for the higher elevation. The problem at this station was to approximately determine the heads to which the pumps would generally work, so as to get the greatest efficiency out of them. The pumps were directly connected to the mains fed from the main pumping station, and about 75 feet below the level of the reservoir that the main station fed.

It is stated by Engineer Macallum that besides the usual annual and daily fluctuations in head with the added effect of the draft of these pumps on the static head was the difference in level of two reservoirs on the main system to be considered. One of these reservoirs was only used in case of emergency, or while repairing or cleaning the reservoir generally used, but as it was 60 feet lower in elevation and two miles distant across the city, and nearer the pumping station, it materially produced considerable variation and practically made the problem of obtaining maximum efficiency with turbine pumps under all working conditions indeterminate.

The pumps as built and operated give a maximum efficiency of 60 per cent.. although under certain conditions the specified efficiency of 75% is obtained. Tenders for these four pumps in place varied from $6,000 to $6,800. The main pumps are driven by 750 h.p. motors, the lower level pumps at the booster by 50 h.p. motors, and the higher level by 130 h.p. motors. All these pumps at 750 r.p.m. There were in commission from the main pumping station three rising mains 30 in., 20 in. and 18 in., respectively, being connected to the pumps in the usual haphazard way prevalent throughout many places in this country. It was decided to build a fourth main 36 inches in diameter and about equal to the other three mains in discharging capacity. Although nearly two miles of this main had to be built to bring to the outskirts of the city along a pipe line already used by the other three mains, it was decided to take a slightly longer route away from this pipe to avoid the danger of a bad blow-out putting all the mains out of commission.

FIG. 3— 48 IN. INTAKE PIPES IN 140 FT. LENGTHS.

The connections from the pumps were

FIG. 4— 30 IN. VALVE TO MAIN 48 IN. HEADER.

carried to a header pipe four feet in diameter, running at right angles and at a lower elevation than these connecting pipes. Between each of the old pipes and the header a gate valve was placed and as the new 36 in. main went off from the end of the header the whole arrangement proved very flexible in operation. On each of the mains was the usual check and gate valves, besides the venturi tube for measuring the discharge. Before laying the large main to the city and other mains throughout the city, tests were made to ascertain the relative efficiency in speed in making poured lead wool joints, also the relative efficiency of joints caulked by pneumatic hammers or by the usual hand method. It was found that with the pnuematic hammers, between four and five joints could be caulked with a poured lead joint to one by using lead wool.

It is of interest to note that the city had a small steam shovel with a half yard dipper which did the excavating and also the lifting of the pipe into the trench. A 12 ton dinky engine with cars and track cars was purchased and with this equipment (which also did the back filling) as high as fifteen 36 inch pipe were laid in a day in a trench which had a variable depth but always sufficient to give a top covering over the pipe of five and a half feet. This large main was laid to grade with blow offs every half mile to the city and having the usual gate and relief valves. The length in feet of new mains in this reconstruction comprised 12,900 ft. of 36 in. pipe and 138,000 ft. of 30 in. pipe, also 6,000 ft. of 24 in. pipe, the 20 in. and 18 in. pipe being 4,600 ft. and 2,500 ft. in length respectively. Engineer Macallum gives the total cost of this work including intake, conduit pumping stations and mains as three quarters of a million dollars.

AIR-CYLINDER LUBRICATION

In looking over some of the recent issues of "Coal Age," my attention was attracted to the inquiry of an engineer who had experienced trouble in the lubrication of the air cylinder of his compressor, and asked for information in regard to the best lubricant to use for that purpose. I have had some experience in the lubrication of cylinders and can appreciate the correspondent's position fully.

Although everything stated in the reply to this inquiry is quite true, I was surprised to find that the writer omitted to mention one of the best air-compressor lubricants manufactured or used. I refer to flake graphite, which has no equal as a lubricant not only in air-compression practice, but likewise for steam engines, gas engines, journals, valves, and, in fact, wherever a lubricant of superior quality is required.

Lubricating Qualities of Flake Graphite

Flake graphite possesses peculiar properities not found to the same degree in other lubricants. For example, its structure is such that it fills up or overlaps the roughness of metallic bearing surfaces. As it is well known, graphite has a strong tendency to attach itself to a metal surface and quickly imparts to it a superficial glaze that almost eliminates friction.

Again, as a lubricant, graphite is not only more enduring than oil, but possesses the important feature of withstanding a high degree of heat. It is this feature particularly that adapts it to the lubrication of air-compressor and gas-engine cylinders, where the heat is sufficient to volatilize or carbonize the oil and render it useless as a lubricant under such conditions.

Everyone who is familiar with the operation of air compressors or gas engines freely admits that oil has many disadvantages that render its use inefficient and often harmful. The use of graphite for the purposes named would have become universal long since had it not been for the difficulty encountered in introducing the graphite into the engine cylinder.

That difficulty, however, is more imaginary than real. Special devices have since been made for automatically feeding flake graphite into cylinders and on all bearing surfaces that must be lubricated. One of these devices is known as the Winans Dry Graphite Lubricator; another, Johnson Graphite Lubricator. It is claimed for each of these that from 50 to 60 per cent. is saved in the cost of lubrication by the use of graphite instead of oil.

In my practice, I have been using Dixon's Ticonderga Flake Graphite for the lubrication of air-compressor and gas-engine cylinders, as well as on the other moving parts, in all classes of mechanical equipment. Permit me to name a few of the advantages I have found that graphite possesses over oil when used as a lubricant. They are as follows:

Graphite, in lubrication, (1) is unaffected by high-temperatures; (2) cannot be carbonized or ignited; (3) cannot give off explosive vapors; (4) does not clog discharge valves; (5) will not accumulate dust or grit; (6) enables a large saving in cost of lubrication; (7) avoids danger of explosion in air-compression practice.

Last, but not least, I have found that the use of graphite in cylinders improves the fit of the piston, while at the same time reducing friction, making repairs less frequent and saving trouble and expense.

—An Engineer, in "Coal Age," from "Graphite."

CHEAPER ELECTRIC WIRING

A special committee of the Institution of Electrical Engineers (Great Britain), has been formed to consider the revision of the existing rules for electric wiring in buildings. This committee is the outcome of a growing conviction that the high quality of British cables and accessories justifies a relaxation of the standards hitherto imposed. During the war an enormous number of army buildings have been wired on the surface and in other ways not consistent with standard British practice, and the experience that is gained will be turned into account in cheapening the cost of installation and materials. British manufacturers of wires, switches, insulators, and other accessories will thus be led to expand the production of types which will be peculiarly adapted to meet the needs of overseas markets. Satisfactory quality will be ensured by the National Electric Proving House which is about to be established in Great Britain. The Proving House will put the hall mark of good design, material, and workmanship on every class of electrical apparatus, thus giving British productions the full benefit of the high reputation they have always held.

LEARNING SOMETHING NEW

A reader of POWER HOUSE writes: "I look over the advertisements the first thing for new machines or new advertisers. I thereby learn something about machines I may never see." The value of looking over the advertisements of POWER HOUSE lies in the information gained regarding new equipment, etc. The more the engineer knows about efficiency in equipment the more up-to-date will he be in his ideas. He will become more efficient himself, too, and his advice will be sought by the company when new equipment is being selected. Our advertisers take great pains with the preparation of their message, and this is appreciated by POWER HOUSE readers.

The Use of Oil and Powdered Coal as Fuel

In a Paper Read Before the International Railway Fuel Association and Reported in Power Plant Engineering, the Author Gives Some Interesting Data Relative to the Use of Both Fuel Oil and Powdered Coal in the Production of Steam

By JOSEPH HARRINGTON

As the situation exists to-day, crude or fuel oil forms almost the only fuel in use for heating the small industrial furnace. This fuel has been developed in its application to a high degree of refinement.

As it comes from the ground, as the so-called crude oil, it contains the entire series of hydrocarbon compounds, although not always in the same proportions. Western oils are as a rule richer in the heavier constituents, while those from Pennsylvania contain more of the lighter or more volatile elements. Another broad division as to character is determined by the nature of the residuum left when all the volatiles are removed. Certain oils, when subjected to complete distillation, leave an asphaltic substance, and others a paraffin. These so-called "bases" seem to be the body or element binding the parts together and determining the "weight" of the oil. The words "heavy" and "light" are terms indicating in a general way the proportion of base in the oil being described. This base, being in solution in the lighter and more fluid parts, affects the density or specific gravity to a marked degree. Since the base is a combustible hydrocarbon, it follows that an increase in density increases the number of heat units in a given volume, the gallon being the volumetric unit commonly used in the oil trade.

Following this line of reasoning, it would seem that of two oils offered for sale, one weighing 7 lb. and the other 7½ lb. per gallon, the latter would contain the greater number of heat units. This is actually the case, the purchaser getting about seven per cent. more heat in each gallon.

There is a practical limit, however, to the extent to which one can apply this reasoning. As the density of the oil increases, the fluidity decreases, and difficulties are encountered in pipe lines and nozzles. Increased temperature will offset to a large degree the tendency toward viscosity, and care must be taken, if heavy oils are to be burned, to provide adequate heating facilities, both at the tank and along the pipe lines.

At the burner also increased air pressure must be provided, or difficulty will be had in properly atomizing the oil. The necessity for complete atomization increases as the density of the oil increases, since the natural volatility is becoming less. This is a function of the "oil burner," which is strictly a misnomer when applied, as it so often is, to the nozzle or injector. The combustion chamber really deserves this name if any one part of the combination is to be so called.

An astonishing number and variety of oil feeding devices have been devised and built, and the subject of injecting oil fuel into a furnace for combustion purposes has been the subject of the most elaborate and extensive experimentation. It is therefore to-day a highly developed branch of combustion engineering, so that it is relatively definitely defined in its methods and results. Oil is a more uniform fuel than coal, and it is a most interesting thing to note that the heat value per pound is about the same, whatever kind or density is taken. Crude oil varies from 18,500 to 20,000 B. t. u. per pound, and if the constituent parts are tested the same range of heat values are obtained. Accurate heat determination is more difficult than with coal, and similar samples will apparently show as much as 500 or 600 B. t. u. difference.

On the whole, however, the fluid fuel can be fed to a furnace with considerable uniformity, air supply can be nicely regulated and combustion efficiency secured and maintained.

There are two general principles upon which oil feeding is based, and these will be described in order.

The first method is one which depends upon the heat of the furnace and its incandescent brickwork to volatilize the oil and put it in shape for rapid combustion. This in a sense is a gasification of the oil from bulk state. Oil is injected into a furnace of high temperature, and a rapid absorption of heat causes the liquid to vaporize and rise to the ignition temperature. In this state it becomes highly inflammable and burns with an intense heat. If the furnace, however, is not in suitable condition for the quick volatilization of the liquid, the combustion is delayed and heat is developed beyond the point where it is most desired.

The essential weakness of this method lies in its dependency on the furnace heat for volatilization of the oil. There are two variables here to contend with: first, the volatility of the oil itself and, second, the furnace temperature. Both may and do vary. Another defect of this method is the fact that if too high pressures are used for the furnace served, some of the oil may actually reach the distant wall in liquid state, and, by adhering thereto, become carbonized and partially lost. Not only may this be the case, but the temperature may be so intense from the blowpipe action of the oil jet, that destruction to the brickwork may result. A final variable is the changes in oil or air pressures.

The second method is the mechanical vaporization of the oil by means of a spray head or nozzle arranged in such a manner that the oil is of necessity divided into very fine particles or globules. In this condition the amount of exposed surface relative to the volume of oil becomes greatly increased, and oxidation may proceed with the utmost rapidity and completeness. This system differentiates very sharply between the gasification or volatilization of the liquid by virtue of a highly perfected mechanical subdivision. It is obvious that a liquid may be so finely divided that it will remain in suspension an appreciable time, like a cloud of steam. This is what is commonly observed in the case of water with lawn sprinklers or cooling nozzles for spray cooling.

If this process is effected by means of compressed air, it can be accomplished with about 20 per cent. of air required for the complete oxidation of the fuel. A basic fact must not be overlooked in this connection: The very idea of mechanical atomization carries with it the thought of a diffusion of spray in a volume of air, and the surrounding of each globule with an atmosphere of air. It is an easy step, therefore, both in one's mental conception of this condition, and in the actual furnace, to add and intimately mix more air to the now gaseous fuel. If this air is injected by mechanical means in such a manner as to blend rapidly with the cloud of oil spray, the flame takes on the character of the Bunsen burner flame, the mixture being perfect and the temperatures exceedingly high. It is quite possible, however, to induce the balance of the air requirements through adjustable ports or openings surrounding the spray nozzle. When the oil spray, with its portion of carrying air, is given a swirling or spiral motion, it has a decided tendency to disperse under the action of centrifugal force, largely losing its axial velocity. Under these conditions it is noted that the combustion takes place right up to the tip of the burner and melting temperatures may be obtained within 6 or 8 in.

An important means of judging the temperature of a flame is by its color or luminosity. The luminous element is the carbon particles heated to incandescence just before being burned or oxidized. Aside from the fact that such particles are a part of the flame and

that they are an index of the flame temperature, contributing their share of heat thereto, they have no exclusive monopoly of the temperature control, and are not a necessary adjunct to high gaseous temperatures.

The Bunsen burner produces an almost invisible flame, yet high temperatures may be developed. A proper atomization of fuel oil and commingling with the right amount of air will produce the elements of perfect combustion. The flame will be short and intensely hot, and will not fill the furnace with a great luminosity, yet the furnace temperature may be much higher than when full of flame. This is the principle underlying the Billow system.

Much has been said in regard to the destructiveness of the oil flame at close quarters, and efforts have been unceasing to find a refractory substance which is able to withstand the high temperatures developed. One of the fundamental principles of furnace design is that the temperature is directly affected by the proximity of the furnace walls and roof.

At the present time, and probably for some years to come, all refinements in the selection or purchase of fuel oil must be forgotten. Users are fortunate in being able to get anything that will burn, and prices are several times those of a year or so ago. The tremendous demand for motor fuels and the ever-increasing requirements of certain special industrial processes tax the country's output to the limit and render a consideration of other fuels timely and appropriate.

Powdered Coal

Engineers have recently become much interested in the use of powdered coal as fuel for furnaces. Fulfilling as it does the requirements of a gaseous fuel, it combines the possibility of high efficiency with a cost indicative of great economy.

It is unnecessary to give the specifications for pulverized coal, but I would like to emphasize the fact that in certain classes of service an extra fine grind repays the trouble and expense of obtaining it. Coarse coal results in offsetting substantially all of the fundamental advantages of pulverized coal, and too great care cannot be given to this item.

It is entirely possible to adapt this fuel to any size of furnace. It is a fuel of such a nature that intelligent care must be expended on the furnace design and application thereto. There is nothing in the nature of this fuel to prevent its successful use on any scale whatsoever. Powdered coal nozzles or so-called burners are being made, scarcely an inch in diameter. Those required for the larger furnaces may run up to 18 in. in diameter. The pressure of the air required for its introduction must be carefully controlled and adapted to the particular service. Ordinarily the pressure should be as low as possible, and dust introduced in a slow rolling cloud, widely diffused.

On account of the independent control of both fuel and air, it is readily possible to obtain any gas analysis that may be desired. I show a tabulation which illustrates some actual gas analyses taken by the writer in an annealing oven. The air in this case was held at a constant volume, the amount of coal varied by means of speed control in use at this plant. This was a variable speed motor with a 10-point rheostat. When the maximum CO_2 was reached, CO began to develop because of the limitation to combustion imposed by the size of the furnace. If coal had been introduced in still further amount, CO would have amounted to a considerable percentage, and the CO_2 would have been appreciably reduced. We would then have had almost a gas producer effect, under which condition the furnace temperature would have rapidly declined.

Gas Analyses

Air Supply Constant		Coal-Supply Constant	
Rheostat Point No.	CO^2 at Flue	Air Gate Notch No.	CO^2 at Flue
1	13.1	1 (open)	13.0
2	14.0	2	14.0
3	14.1	3	14.5
4	15.9	4	15.7
5	16.3	5	15.7
6	16.8		
7	17.1		
8	17.1 (smoky flame)		

The question of furnace temperature enters into this consideration just as it does in the case of oil. It is quite as possible to melt out an entire interior of a furnace with powdered coal, and economy of fuel and floor space almost always dictate the furnace design. In a given furnace the temperature rises as the excess of air is cut off, and this may be so great as to be destructive. At the same time, however, it must not be forgotten that reduction of excess air may be carried to the limit without excessive temperatures, if the furnace proportions bear the correct relation to the amount of coal fed per unit of time. In the furnace from which the gas analyses above quoted were taken, the temperature was maintained constant at 1500 deg. F., and at the same time between 17 and 18 per cent. of CO_2 was developed. This furnace, however, had about 200 cu. ft. of cubical contents per pound of coal per minute. If this had been 10 cu. ft. with the same amount of coal per minute, temperatures would have been developed which would have melted the brickwork rapidly.

I quote these two figures because they happen to be actual cases wherein temperatures were observed. Intermediate temperatures would have been obtained with volumes between the two limits stated. It is therefore a possibility that high combustion efficiency can be obtained without the production of destructive temperatures.

Powdered coal really takes on the character of gas when diffused throughout a current of air. Its finely divided condition permits it to be carried in suspension for an almost indefinite time, provided the velocity of the carrying current is maintained. It is quite possible, therefore, to supply a series of widely separated furnaces with this fuel by means of a pipe line, much the same as would be the case with a directly gaseous fuel. The advocates of powdered coal call attention particularly to the marked advantage this fuel has over oil as to cost. With a 12,000 B.t.u. coal at $2 a ton and fuel oil at 3½c a gallon, 1c will purchase 3.2 times as much heat in the form of coal as in the form of oil. While no reference has been made in this paper to natural gas as a fuel, it is interesting to include it in a tabulation design to illustrate the relation between the amount of heat purchasable with 1c. and the amount purchasable in the form of oil and coal. In this case prices existing at the present time are used, and a fairly good grade of Pittsburgh coal is considered.

Comparative Purchasing Power of One Cent

Oil—

B.t.u. per lb.	19,000
Weight per gal.	7 lb.
B.t.u. per gal.	133,000
Cost per gal.	5c.
B.t.u. for 1 cent.	26,600

Gas—

B.t.u. per cu. ft.	960
B.t.u. per 1,000 cu. ft.	960,000
Cost per 1,000 cu. ft.	25c.
B.t.u. for 1 cent	38,400

Coal—

B.t.u. per lb.	14,000
B.t.u. per ton	28,000,000
Cost per ton	$3.00
B.t.u. for 1 cent	93,333

Ratios—

1 cent will buy 1.44 times more heat in gas than oil.

1 cent will buy 3.54 times more heat in coal than oil.

1 cent will buy 2.43 times more heat in coal than gas.

Coal can be sold for $10.62 per ton and equal oil at 5c. per gallon.

Coal can be sold for $7.29 per ton and equal gas at 25c. per 1,000 cu. ft.

Oil would have to be bought for 1.4c. per gal. to equal coal at $3 per ton.

Gas would have to be bought for 10.7c. per 1,000 cu. ft. to equal coal at $3 per ton.

A rather marked difference is noticed in favor of the coal, which goes far in paying for the initial cost of the pulverizing plant. The cost of coal preparation per ton has been given by Mr. Robinson. I shall briefly quote the tables showing these figures:

Capacity of Plant in Short Tons per Hour.	Average Total Cost for Preparation per Short Ton.
2	from 25 to 50c.
3	from 20 to 45c.
4	from 16 to 40c.
5	from 14 to 35c.
10	from 12 to 30c.
25	from 10 to 20c.

The fuel required for drying the coal will average from 1 to 2 per cent. of the coal dried.

The distribution of the total cost may be approximately stated as:

Fuel for drying	10 per cent.
Power for operation	30 per cent.
Labor	30 per cent.
Maintenance and supplies	25 per cent.
Interest, taxes, insurance and depreciation	5 per cent.
Total	100 per cent.

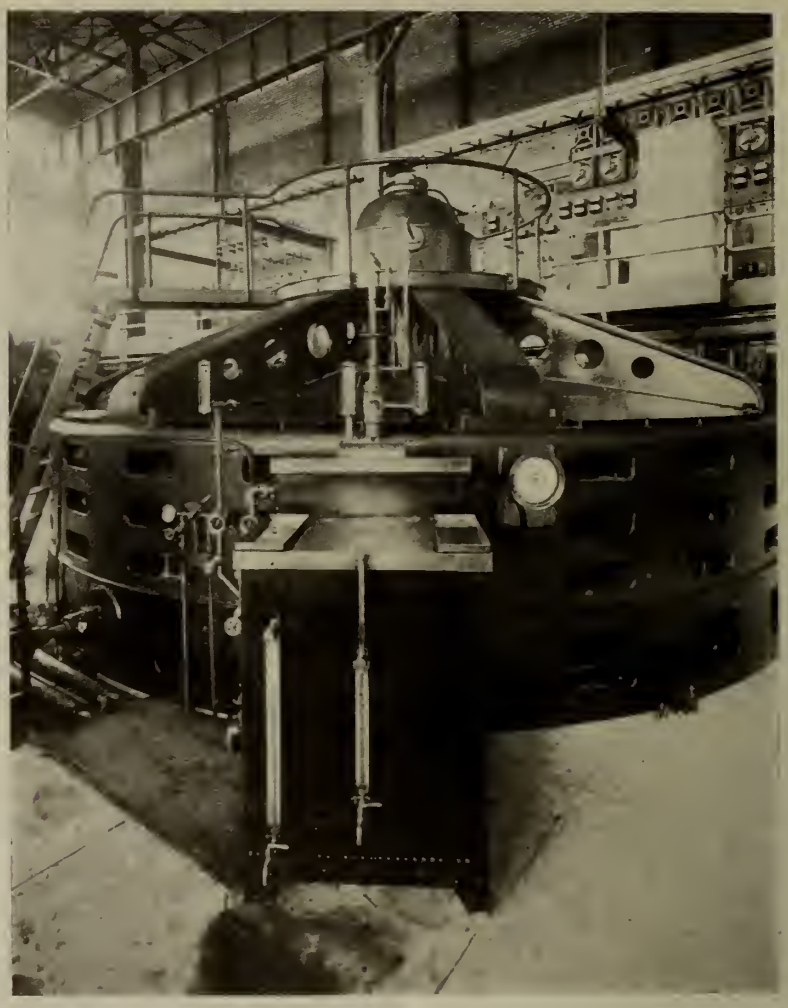
One of the matters most frequently mentioned in connection with this fuel is the disposal of the ash and its effect on the surrounding brickwork. The effect and control of the ash is a topic of sufficient magnitude to form the subject matter of an extended article in itself; and no attempt will be herein made to analyze this subject in detail. In the steam boiler the effect of ash is probably more difficult of control than in the metallurgical furnace. because, as a rule, the ash dust reaching the hearth is not in sufficient quantity to affect operation seriously.

A HYDRO-ELECTRIC OILING SYSTEM

The accompanying illustration shows the efficient equipment developed at Milwaukee, Wis., as a complete oiling system for the installation at the Hydro-Electric plant of Columbia Mills, Minetto, N. Y. The photograph shows the manner in which the oiling system is arranged on each wheel. There are six 2,000 h.p. generators in this station which is equipped with a circulating, cooling and filtering system.

The oil from the thrust bearing and guide bearing flows by gravity to the filter, and after passing through the process of filtration and cooling, it is again returned through these bearings, which is accomplished with a rotary pump, belt driven, from the generator shaft; this pump being located just below the rotor in the base of the machine. All supply and drain lines are furnished with thermometers, indicating at all times the temperature of the oil. It may be mentioned that a recording thermometer is used to record the temperature of the oil in the tub surrounding the bearing, and slight flow indicators are placed in the supply lines leading to the bearings. These indicators show at a glance whether or not oil is flowing, and are provided with electrical connections so that, should the flow of oil cease, an alarm will be turned in at the station switchboard.

Each individual system is designed to filter 3 1-2 gallons of oil per minute and in addition, an emergency system was included which consisted of a filter, not shown in the photograph, together with necessary pumps and overhead storage tanks which are so arranged that in case of failure of the pump or filter on any one of the units, the particular unit affected could be supplied with oil from the emergency system without having to shut down for a moment.



OILING SYSTEM APPLIED TO HYDRO-ELECTRIC SYSTEM.

POSITION OF BOILER FEED VALVES

By M. E.

It is usual to place the boiler feed valve somewhere near the surface of the water in the boiler, so as to avoid, as far as possible, the possibility of the cold feed water from coming in contact with the boiler plates or the furnaces. This tends to reduce distortion of the plates and consequent corrosion. It must not be forgotten that even when a feed-water heater raises the temperature of the feed to approximately 212 F., this temperature is considerably lower than that of the boiling water in the high-pressure boilers such as are widely employed at the present time, and therefore, the distortion referred to above is very liable to occur unless great care is paid to the question of design and the locality of the inlet pipes. In his paper on "Feeding and circulating the water in steam boilers," Mr. John Watson suggested the use of a device to automatically raise the temperature of the feed water to something approaching that of the water in the boiler, and he advocated the placing of the device low down in the boiler at its coolest part, thereby reducing the possibility of distortion, and at the same time assisting the natural circulation of the water. The idea certainly appears to be a good one, and it would be a good thing if experiments could be performed in order to test the value of the arrangement. In another type of feed valve, which is being tried on certain railway locomotives, the feed is introduced through a valve on the tap of the drum, in the form of a very fine spray, so that by the time it reaches the surface of the water in the boiler its temperature is probably not very different from that of the water itself. This device is also worthy of being tried on marine boilers. It may be found, of course, that it tends to cause priming, although where superheaters are employed no trouble need be feared on this account.

PROPOSED CENTENARY FOR JAMES WATTS

The Mayor of Birmingham has called a meeting with the object of organizing a centenary memorial celebration in honor of the inventor of the steam engine. The engineers of Birmingham have decided that a James Watt chair of engineering ought to be founded at the Birmingham University, and that a James Watt memorial building should be erected.

Watt, it will be remembered, was born at Greenock in Scotland in the year 1736. He died in Birmingham in 1819.

Power Plant Management; Coal and Ash Handling

PART IV

This Article in Continuation of Former Articles on the Same Subject Takes Up the Vacuum and Steam Jet Ash Conveyors and Deals With Their Installation in the Power Plant

By ROBERT JUNE, Mechanical Engineer

IF there arises in the mind of any reader of these articles on power plant management, a question as to why we have paid such detailed attention to the matter of the selection of economical systems of coal and ash handling equipment, let us say at once that it is easily the most difficult problem confronting the power plant operator. On no other question is it so easy to make a costly and almost irremediable mistake. Nowhere is it harder to be dogmatic in assertion regarding the merits of any particular system for a given set of power plant conditions.

With a dozen possible systems to choose from, each costing from a few thousands to tens of thousands of dollars, depending upon the size of the plant, the power plant operator may be excused if he throws up his hands in despair. The situation is not made easier by the practical necessity which he is under to make a choice. The increased cost of labor and coal, together with the uncertainty regarding deliveries of the latter, have made imperative adequate coal storage and economy in the cost of handling coal from the time it reaches the power plant yard to its final disposition in the form of ashes.

In our previous articles, we have discussed the applications and limitations of various types of chain and belt conveyors, telphers and skip hoists. We have indicated the desirability of separating the coal and ash handling systems, but have yet to examine two of the most important systems of ash disposal—the vacuum and steam jet systems.

Vacuum Conveyors

In the vacuum conveyor, a line of hard cast iron pipe is extended from the ash pit, or if there is no ash pit, from a point under the boiler room floor, immediately in front of the furnace, to an air-tight ash storage tank. Vacuum is established in the storage tank by a motor or steam turbine drive centrifugal exhauster. An air washer is installed between the storage tank and the exhauster, to remove ash dust from the expelled air.

When the exhauster is in operation a current of air, moving at very high velocity, is produced in the pipe through an intake port at the end of the line. Ashes, when introduced, are whisked through the pipe and into the storage tank.

The advantages of this system are:

1. Flexibility: The pipe can be carried in any direction, up or down, right or left, with discharge point a considerable distance from boiler-room.

2. Adaptability: Easily installed in all types of boiler-rooms, old and new.

The disadvantages are:

1. Limitations of Service: Ashes can only be removed from one furnace at a time, as the opening of an intake near the tank will destroy the velocity at an intake farther away. Only about 2,500 to 3,500 h.p. of boilers can be served by a single system—above that h.p. additional complete systems must be installed.

2. Leakage: Both pipe line and tank must be maintained in an air-tight condition at all times.

3. Explosions: There is danger of explosion of ash dust and gases in the storage tank. The introduction of water into the pipe line has been tried in an effort to overcome this, but the success of such a means is doubtful, since a sufficient quantity of water to quench the ashes thoroughly will probably prove enough to choke the pipe with wet ashes. Water will also cause trouble by freezing the ashes in the tank in cold weather. and packing them so that their removal is difficult in other seasons.

4. Maintenance: As in all ash removal systems, except the skip hoist, maintenance is high on account of the abrasive character of the ashes. Pipe renewals, especially bends, can be expected after 6,000 to 8,000 tons of ashes have been handled. Exhauster repairs, especially to the impeller blades, are to be expected, due to some ash dust coming through the air washer.

STEAM JET CONVEYOR INSTALLED BELOW ASH PIT.

Steam Jet Conveyor

Like the vacuum conveyor, the steam jet conveyor primarily consists of a pipe line into which the ashes are fed, and through which they are transported to a discharge point. The similarity between the two systems is not great, however. In the vacuum conveyor the ashes are moved by suction through the entire length of the pipe line, while in the steam jet conveyor, suction is employed only in what is called the suction line immediately in front of the boilers or ash pits.

Suction is created by the action of high velocity live steam discharged into the centre of the pipe-line, in the direction of travel of the ashes. The steam discharge tends to create a vacuum behind it, which in turn creates a current of air through the air intake at the end of the line, similar to the action of the vacuum conveyor. The effective suction distance of one steam jet is, of course, limited, and if this discharge is exceeded, it is necessary to install booster jets. The discharge of the ashes beyond the steam jet is really an objection due to the force of the jet actually pushing the ashes through the pipe, hence the effective discharge distance of a steam unit is much greater than its suction distance, therefore in the average system no additional steam jets are necessary in the discharge line.

The advantages of the steam jet conveyor are :

1. Flexibility: Pipe can be carried in any direction. Any type of discharge may be used, as for instance,

(a) Where it is desired to fill a gully, or other low ground, the ashes are merely blown from the end of the pipe without any restraint. As the ashes are blown 50 to 75 feet beyond the end of the pipes, some ashdust will be carried over the neighborhood, even when the most effective water jet is installed in the line.

(b) For loading cars, wagons, etc., a baffle box may be used. Some trouble due to the dust may be anticipated with this system, but if properly designed the dust may be so minimized as not to be objectionable in manufacturing districts.

(c) Where an ash storage bin is desired, the most careful attention must be paid to design, so that no dust will be discharged with the exhaust steam; no trouble will be caused by water of condensation; no water will be allowed to come in direct contact with the ashes in the bin; ashes will be discharged into the bin without any remaining downward compound of the conveyor force, which will cause packing; impact of the incoming ashes must be taken by a suitable baffle, as ashes discharged against the bin walls will soon cut holes through them.

2. Adaptability: Can be installed in practically any plant, no matter how crowded.

3. Low Initial Cost: Owing to simplicity and freedom from mechanism, this is probably the cheapest effective system, so far as first cost is concerned, which can be installed.

The disadvantages of the steam jet conveyor are:

1. Clinkers: Clinkers must be broken to size to pass through intake openings. Under average conditions, burning run-of-mine bituminous coal, this is not a serious disadvantage, as clinkers can usually be easily broken with the hoe. In cases, however, where the ash produced is made up almost entirely of large hard clinkers, steam jet conveyors should not be considered.

2. Steam Pressure: Not less than 80 lbs. of pressure is required.

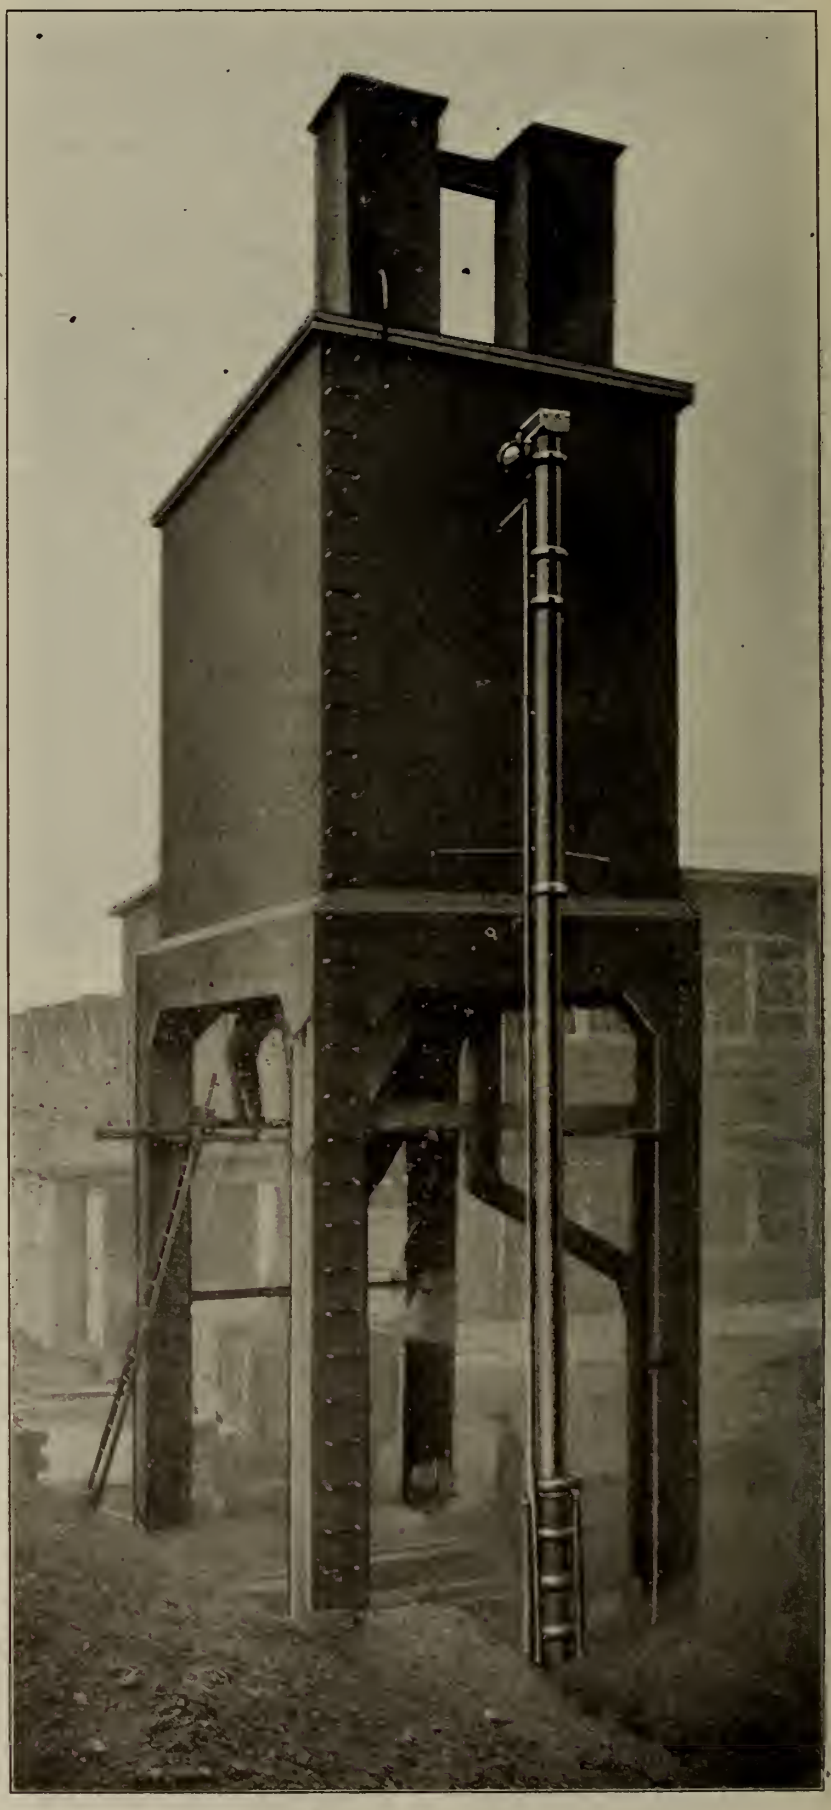
3. Wet Ashes: Generally speaking, wet ashes cannot be handled on account of packing at turns in the line. This eliminates certain types of installations, as for instance, water-sealed gas producers.

4. Limited Capacity: 2,500 to 3,500 h.p. of boilers is about all which can be handled by a single system; above that h.p. additional systems must be employed.

5. Maintenance: The abrasive character of the ashes render pipe renewals, especially at bends, an expected occurrence after 6,000 to 8,000 tons of ashes have been handled. In order to cut down renewal expenses, elbows are made with removable backs, and where possible long sweep bends are employed.

6. Ash Freezing: Ash freezing in storage tanks is to be looked out for in cold weather.

An idea of steam cost for a typical



TYPICAL STEAM JET CONVEYOR STORAGE BIN.

steam jet conveyor system may be obtained from Table I:

TABLE I

Boiler No.	Distance from Ejector.	Steam Pressure.	Quantity of Ashes Moved	Time.	Tons per Hour.	Pounds Steam Used per Min.	Steam Used per Ton Ashes Moved	Cost of Steam per Ton Ashes Moved.
1	4 ft.	110	300 lbs.	1'0"	9 00	37. 3	349.3	$.068
2	19 ft.	109	292 lbs.	1'0"	8.79	37 10	253.2	.07
3	35 ft.	109	284 lbs.	1'0"	8.45	37.10	274.9	.078
4	52 ft.	108	234 lbs.	1'0"	7 04	36.85	314.0	.088
5	64 ft.	109	210 lbs.	1'0"	6.30	37.10	353.3	.098
Average	34' 8"	109	264 lbs.	1'0"	7.92	37.10	289.0	$.080

As indicative of the labor saving effected by a conveyor of this type, one user reports the elimination of 1 ash wheeler, 1 teamster and 1 horse, at a saving of $12.00 per day. Conditions are described as follows:

"The only expense for maintenance, after six months' constant operation, was the replacement of the first section, beyond the steam nozzle, which was completely worn out. The conveyor handles the ashes from a battery of five (50) 150 h.p. boilers, and one 500 h.p. boiler. The coal used is a fine dirty slack, stored on the open prairie, and containing, owing to the inclusion of mining machine dirt, about 25 per cent. of ash. The ashes are left on boiler room floor in front of boiler until cleaning is completed, and are then put into conveyor, which handles the complete cleaning in about seven minutes. The grade conveyor pipe line rises about 80 per cent. for 200 feet, then 45 per cent. for about 40 feet, discharging onto an open pile."

Determining Class of Equipment to be Installed—By Calculation

We have now discussed all the important types of coal and ash handling equipment. Regarding our ash conveyor question as disposed of, let us give a final glance at the problem of making an intelligent selection between flight, pivoted bucket, and belt conveyors for coal handling.

Reginald Trautschold is authority for the following table of annual operating costs:

TABLE II

ANNUAL OPERATING COSTS IN DOLLARS PER TON-MILE

Equipment	Fixed Charges	Operating Expenses	Power Expenses
Flight Conveyors (including 20% elevation)	17.5/N	0.55	5.30 Pc.
Belt Conveyors (including 20% elevation)	109.5/N	0.15	2.15 Pc.
Pivoted Bucket Carriers (including 33 1-3% elevation)	520.0/N	0.40	2.65 Pc.

N—equals hours per year equipment is in operation.
Pc—equals cost of power per horsepower.

As an example of methods of determining by calculation the type of equipment to be installed, let us assume that a power plant requires 40,000 tons of coal a year, and that the distance from the track hopper or point of delivery to the far end of the conveying system is 440 ft., we have thus 3,333 ton miles per year. Let us also assume that when in operation the conveyor system must handle 80 tons per hour.

We know that the initial cost of the belt conveyor will be considerably heavier than that of the flight conveyor, but our choice will be governed by consideration of costs per ton moved, as well as initial costs.

SAMPLE CALCULATIONS

(a) Flight Conveyor System: 40,000 tons annually.
440 ft., 80 tons per hour.
Power cost, 2c per HP.
Hours of operation $\frac{40{,}000}{80}$ equals 500 hrs. per year.
Annual cost: Refer to Table II.

3,333	x $\frac{17.5}{500}$	equals	$116.65
0.55	x 3,333	equals	1833.15
5.30	x 3,333 x .02	"	353.30
Total			..$2303.10 or 5.76c ton

(b) Belt Conveyor: Same conditions as (a)
Annual cost:

3,333	x $\frac{109.5}{500}$	equals	$729.93
0.15	x 3,333	equals	499.95
2.15	x 3,333 x .02	"	153.31
Total			..$1403.19 or 3.66c ton

(c) Pivoted Bucket Carries: Same conditions as (a), except length, which is 220 ft. Service 1,667 ton-miles per year.
Annual cost:

1,667	x $\frac{520}{500}$	equals	$1733.67
0.40	x 1,667	equals	666.70
2.65	x 1,667 x .02	"	88.35
Total			..$2488.72 or 6.22c ton

The foregoing examples are, of course, merely illustrative of the principles of calculation. If conditions were changed, the results would not be relatively the same. Nor do such figures alone tell the story, since it must be remembered that the pivoted bucket carrier could be used for ash handling as well. The one rule then is to take a given set of plant conditions and to work out the actual costs of installation and operation for each of all these various types of conveyors, which might be installed. Only by thorough investigation can the proper equipment for any plant be chosen.

Some experiments, the results of which are recorded in the "Journal" of the American Leather Chemical Association, have been carried out with the object of determining the wearing qualities of leather from different parts of the hide. They showed that leather from the butt wore on an average at least twice as long as that from the belly portion of the hide, and about one and one-third times as long as that from the shoulder portion.

The relative merits of different classes of explosives were given by Professor J. Young in a recent lecture, as follows: Where the material is to be displaced, but not shattered, a slow-acting explosive is required. Black gun-powder, with a velocity of explosion of 300 m. per second, is good. Blasting powder is still slower in action, and is suitable for quarrying where stone has to be obtained in large blocks. Bobbinite, still slower in action, is much used in coal mines with soft coal. All these are comparatively weak explosives, and large charges are required. Where great power and rending effect, with a moderate shattering effect, is required there is little to choose between the ammonium nitrate class and the perchlorate explosives, except that the former are the safer to handle, but most susceptible to moisture. Some grades of amatol made for military use would also be suitable, and vast quantities should now be available. Where the greatest power in the smallest bulk is required—this will be the case where hard rocks are to be blasted and small drills are used—the nitroglycerine explosives are decidedly best, as they have a high density, great power, and a high velocity of detonation.

A letter from "Over There" tells of the first experience in the trenches of a negro waiter who had been boasting of the things he meant to do to the Germans when he got a chance. Arrived in the first line ditch, Rastus (the other half of his name seems to have been lost somewhere in the shuffle) climbed over on the firing step and glared over in the direction of the enemy. Then, waving his rifle aloft, he shouted:

"Hey, dere, you Bush solders, show me sumpin! Come on, you Kaiser! Come on, you Kruppses! Gimme some dem bombs! Gimme some scrapnel! Gimme some shells on toas'! Gimme 'em! Das all, jes gimme 'em!"

About that time a big shell exploded about 50 feet from where the doughty ex-waiter was standing, the concussion knocking him head over heels back into the trench. Ruefully he fumbled his person to see if he had been wounded.

"Well," he said as he gingerly touched himself here and there, "you kin say whutcher please about dem Germans, but they sho do give service!" — Exchange.

Factors Affecting the Proper Area of Safety Valves

The Following Article Was Received in Response to a Question Asked in Our Question Box, April 5th Issue. The Information Given is Interesting From the Standpoint of Design and Proportioning of Safety Valves

By J. E. MacCORMACK

THE recommended proportion of safety valve area to grate area is one square inch of valve area to two square feet of grate area if the valve is of the ball and lever type, or one square inch of valve area to three square feet of grate area if the valve is a spring loaded "pop" valve.

Other conditions being equal, the larger the grate area the more fuel can be burned, and thus the more steam produced in a given time; therefore, if all other vents are closed, more safety valve area is required to permit this steam to escape without undue accumulation of pressure in the boiler.

The following nominal sizes of pop safety valves have been recommended:

2 in. pop valve for 9.4 sq. ft. of grate surface.

2½ in. pop valve for 14.7 sq. ft. of grate surface.

3 in. pop valve for 21.2 sq. ft. of grate surface.

4 in. pop valve for 37.6 sq. ft. grate surface.

5 in. pop valve for 58.9 sq. ft. grate surface.

6 in. pop valve for 84.8 sq. ft. grate surface.

Although it has been customary to calculate the required safety valve area on the basis of the grate area installed, a (seemingly) more correct method would be to make it proportional to the quantity of steam the boiler is capable of producing, when worked at its full capacity. The reasonableness of this is apparent when one considers the difference between two similar boilers, the one under natural draft, and the other under forced draft. A safety valve adequate for the one might be somewhat too small for the other.

Prof. Rankins' rule is: "Multiply the number of pounds of water evaporated per hour by .006, and the product will be the required area of the valve in square inches." This allows 6-1000 of a sq. in. valve area per each pound of water evaporated per hour. The U. S. Navy Dept. deduced from a series of experiments this rule: "Multiply the number of pounds of water evaporated per hour by .005 and the product will be the area of the valve in square inches." This allows a smaller valve than does Prof. Rankin's rule.

Another method suggested is to calculate the valve area by the area of the heating surface, and the following is a part of a table prepared by a New York firm:

Boiler pressure in pounds above the atmosphere	Area of orifice in square inches for each square foot of heating surface
90	.000796
100	.000719
150	.000481
200	.000364

But as the ratio of heating surface area to grate area varies within wide limits and is not all equally effective, being less effective the further removed from the immediate vicinity of the furnace, the heating surface alone is not a criterion.

Then, too, the pressure carried has a bearing on the subject. A British B.O.T. rule for spring-loaded valves is: "The area of the valve per square foot of grate equals 3.75 divided by the absolute pressure per square inch." In other words, to ascertain the total area, multiply the grate area by 3.75 and divide by the absolute working pressure of the boiler. It will be noticed that in these last two rules the area of the orifice decreases as the pressure increases. This is evidently on the basis that as the pressure increases more steam can escape through a given opening. One might infer from this that a boiler having on it a safety valve only large enough to serve it at a high pressure would require a larger valve in the event of pressure being subsequently materially reduced as a safety precaution, owing to boiler deterioration. On the other hand, however, when valves rise from their seats under increased steam pressures the ratio of lift to area is diminished. This ratio has been carefully determined by experiments covering a considerable range of pressures and records made by tabulation.

Normally, a boiler should be furnished with a steam pipe of a horse power approximating that of the boiler. A rule for determining the capacity in horse power for a given size of pipe is: "Multiply the square of the diameter by six," and by the method of using a ball and lever safety valve with connection below for boiler, side outlet for escaping steam, and another side outlet for steam pipe connection to engine or other steam consumer, the valve will naturally be of a size nominally as large as, or larger than, the nominal size of the steam pipe used. This would appear to be a logical solution of the problem since the duty of the boiler, if used for power purposes only, would, to an appreciable extent, be governed by the size of the steam pipe connecting it with the engine, and as the boiler would most likely be fired accordingly, the safety valve would thus have a direct ratio to the normal rate of combustion adopted, but I have known this suggestion to prove unreliable under some conditions. Another feature that steps in here is the claim made that "the maximum desirable diameter for safety valves is four inches, for beyond this the area and cost increase much more rapidly than the effective discharging capacity." Given two boilers, one having four times as much grate area as the other, and the smaller one requiring a three-inch (diameter) valve, then, if we put a six-inch (diameter) valve on the larger boiler, we have quadrupled the valve area, but have only doubled the circumference around which the steam escapes; thus, to quadruple the area of opening the larger valve must have twice as much lift as the smaller one has, and now, too, we realize a possible chance of misunderstanding printed rules, if uncertain whether they are meant for determining the area of valve face or for determining the area of valve opening, or orifice.

A rule proposed for determining the size of safety valve required for a boiler under given conditions is as follows:

"Find how much water the boiler can possibly evaporate under the given conditions by multiplying the greatest amount of coal which can possibly be burned per square foot of grate surface per hour under the given conditions by the grate surface in square feet and by the greatest number of pounds of water which each pound of coal would evaporate; and provide valve area to amply allow of the discharge of that amount." And to find the necessary area of opening: "Multiply the absolute pressure at which the valve is to be set by 51, and divide the number of pounds of steam possible to be generated per hour, determined as above, by the product." This procedure involves some factors not readily determined with exactness without conducting a series of experiments under the given conditions and recording the data obtained, some of which, however, would not be applicable for use in accurately solving the safety valve problem, where conditions were different. Then after having ascertained the required opening we would necessarily calculate by the circumference of the different valve heads, their bevel and

their (assumed) lift when choosing one from among the nominal or stock sizes; and by calculations involving these factors, determine the nominal size or the particular make and size of valve to install.

It is no new thing to find that a plant designed for a certain work and output has in later years expanded, increased its business and output, or perhaps added side lines, added more machinery, and, owing to the position and original plan of the building, there cannot conveniently be added sufficient additional boiler units to supply the demand for steam when working at a normal capacity; therefore, their boilers become overloaded and are forced if the required amount of steam is provided.

The U. S. Geological Survey Bulletin 367, prepared by Walter T. Ray and Henry Kreisinger, and entitled "The significance of drafts in steam boiler practice," says in the introduction on page 5: "The experiments so far made seem to indicate that it is possible to double or treble the capacity of a plant without making any radical changes in the furnaces and boilers. These increases require about double and treble the quantities of air to be put through the fuel beds and boilers." On page 56 it says: "A caution is in place here. The attempt must not be made to put more air through existing boilers by running the fans a great deal faster, because the power consumed will increase far faster than the above calculations estimate. New fans and engines must usually be installed of sufficiently larger size to supply the larger quantities of air at as high an efficiency, if not higher."

"As has already been suggested, one way of reducing the work required from the fan in the case of doubling the capacity of the boiler is to increase the grate surface, so as to avoid a high increase of pressure drop through the fuel bed, increasing materially only the pressure drop through the boiler proper. A low pressure drop through the fuel bed would also insure better combustion of the fine particles of coal which would be carried out of the stack unburned if high gas velocities through the fuel bed were employed, the high velocities being obtained by high pressure drops."

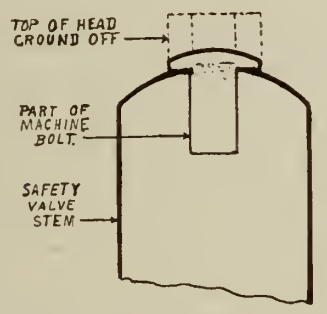
On page 56 it says: "If two or three times the usual amount of gases be forced through a stoker and boiler, so as to produce nearly two or three times as much steam, the total work expended on the fans will be increased perhaps 8 and 27 times respectively (2^3 and 3^3)."

After giving some estimates on steam required for the forms, and giving a couple of tables, it says on page 59:

"Doubling, trebling, and perhaps, with larger grate areas, even quadrupling the rate of working a boiler seems to be sound commercial practice. Furthermore, by carefully designing a fan the above steam consumption could nearly be cut in half. This we must admit if we study efficiency tests made on fans of various makes by trustworthy experimenters, who have shown that the efficiency of a blower from the shaft to air delivered lies ordinarily between 10 and 50 per cent.

Bureau of Mines technical paper 63, entitled "Factors Governing the Combustion of Coal in Boiler Furnaces," says on page 39: "For a rate of firing of 28.4 pounds of coal per square foot per hour, a combustion space of 2.9 cubic feet per square foot of grate area should be sufficient to reduce the combustible content of the flue gas to 0.2 per cent." And a little further on it says: "Practically complete combustion may be obtained, however, with a rate of firing of 60 pounds if the combustion space is more than five cubic feet per square foot of grate area."

It is obvious that for high draft velocities combined with economy especial care is necessary with regard to preventing all air leaks through the setting, though the leaks make less difference if, in the case of mechanically-generated draft, the said draft is produced by a pressure fan at the ash pit and an exhaust fan at the uptake, the effect of their united action being so regulated as to provide the required pressure drop



REPAIR TO SAFETY-VALVE STEM.

through the fire and through the boiler, yet maintain practically atmospheric pressure in the combustion chamber. Then the air pressures inside the setting and those outside the setting at this point will, by nearly balancing each other, minimize the effect of air leaks in the masonry.

The proportion between grate and heating surface should be, to a large extent, determined by kind of fuel to be used, the draft available being also a factor to consider either with a view to increasing it to suit a given fuel or given grate area, or else as a determining factor fixing the minimum of grate area below which it is not practicable to go when using a given fuel. A large grate area lowers the rate of combustion (per sq. ft.) and thus permits the use of inferior grades of fuel, which could not be economically employed in furnaces having a small ratio of grate area to total heating surface. Aside from the use of average steam coal for fuel there is the factor of differently constructed grates with different percentages of opening for other grades of fuel, and in some plants Dutch ovens are installed and others have an increased grate area designed for use with unusual fuels as sawdust, spent tanbark, etc. In such furnaces a change to a good fuel would call for a reduction in grate area used, either by cutting out boiler units or by (if the change was to be for a short time only) removing a portion of the grates and inserting dead plates, for with too large a grate area to admit of using the proper amount of draft for that fuel the combustion rate per unit of area is slower, the furnace temperature is lower, and the waste heat units to the uptake becomes a greater proportional amount of the total heat generated in the furnace, for speaking of low furnace temperatures, it must be remembered that the only heat the boiler can utilize is that due to the difference in temperature between the fire and the water in the boiler. Thus the kind of fuel used, the rate of combustion and the amount of heating surface in the boiler, all modify the amount of grate area desirable.

In summing up all the above we seem to get nowhere, except to realize that numerous factors have a bearing on the safety valve problem. Some of these are rather difficult of determination without the aid of certain indicating devices, which are not always provided, and, anyway, the combined effect varies with individual plants. Obviously, the manufacturer cannot accurately forecast the various conditions under which each of his boilers will ultimately be operated, and in choosing the grate area rule for determining the size of safety valve he has not only as definite a single factor as any to work from, but it is also a factor easily ascertained by any operator at any time, and if the area is increased or decreased later, the operator can estimate that also, and ascertain if his grate area and valve area conform to the rule. Probably the manufacturer assumed that the grate area used would be a length equal to the diameter of the boiler and a width six inches less than the diameter of the boiler, and he put on a safety valve accordingly. At any rate the problem of the size of the safety valve installed is almost always, if not always, determined for the operator, the valve having been already in place when he arrived on the scene. I think the best he can do is to add a second valve if he finds the original one inadequate. I will now give three object lessons from personal experience:

Considerably over a dozen years ago I visited the scene of a boiler explosion. One of the principal machines had failed to operate satisfactorily and the engineer had been signalled to shut the engine down. Before the faulty machine was again put into proper working order, the boiler exploded. When questioned, no one appeared to know where the steam gauge hand was pointing just previous to the explosion, but several had noticed that the safety valve was working for some time, or, at least, a little while before. A number stated that they had, on previous days, been in the boiler room and saw

the steam gauge hand climb to 120 or higher, while steam was escaping at the safety valve, and one man claimed to have seen the hand at 135 lbs. under similar conditions. Wood was the fuel used, and wood embers do not cool down as quickly when draft is reduced as does a bituminous coal fire. Of course, there were legal proceedings about it, but that is an aside from the subject now in hand.

On another occasion and in another mill I went down to the fire hole at a time when the engine was, and had been for some minutes, temporarily shut down. The man in charge and two or three other men were standing in front of the boiler, apparently quite at peace with each other and with the world in general. Steam was escaping from the safety valve and the steam gauge hand was pointing at 120. As I had myself set this safety valve at 110 lbs. some time before this, I now took quick steps to have the heat from the fire still further reduced. Soon the pressure gradually lowered, until at 110 the valve closed again. This valve was a ball and lever type, and of the same nominal size as the steam pipe used. There was a spring pop valve of less than half the area on a discarded nearby boiler, and in the side of the dome of the used boiler just mentioned, there happened to be a plugged hole right size for this pop valve. Next Monday morning before steam was raised the said pop valve, by means of a nipple and elbow, was attached to this used boiler and subsequently set to nearly correspond with the ball and lever one. As a result there was no more accumulation of pressure after it rose enough to open the second valve. The following year the setting was pulled down and rebuilt and the furnace front arrangement changed. The pop valve was removed for re-grinding, and as this job had been neglected and was not yet finished when the plant was ready to be put into operation, it was decided that they would do with but the one valve for a day or two at first. Before long it was found that the changes made had rendered the second valve unnecessary and it was never reinstalled. In this case the differences in the condition of the setting and arrangement of the furnace so modified the amount of control the fireman had over his fire, that it made the difference between requiring, and not requiring, the second safety valve.

Let no one think that in the above criticism I wished to compromise the abilities or character of the man in charge. On the contrary he was a good hand, but in charge of poorly designed equipment.

On one occasion an American was given charge of a steam plant using sawmill coarse refuse for fuel. He brought with him some ideas new to the local operators. One of these ideas was that in this type of plant no bridge wall was required, and accordingly he removed it. He did not (and apparently it was through motives of his own) remain for the full season, and his successor when questioned as to the effect of removing the bridge wall assumed a non-committal and somewhat evasive manner; but in a neighboring plant where the idea was copied as an experiment, it was found that the boiler did not steam easily in the morning until sufficient coals had accumulated behind the grates to (in effect) serve as a bridge wall in so far as directing the course of the products of combustion was concerned. Whuen shutting down, as at noon or night, this bridge of coals (wood embers) continued to give off heat for a time and thus increased the duty of the safety valve at these times and more especially so when an unexpected shutdown occurred during working hours, and might in extreme cases call for the putting on of a small second safety valve. It was anticipated that a new bridge wall would be put in.

Some old safety valves have been worn and reground until the upper edge of the lever is no longer level but slopes downward towards its outer end. This causes the ball to slowly work its way along the lever until the valve no longer lifts at the pre-determined pressure. Different plans have been adopted to prevent this, and some of them may be acceptable, but in any case I prefer to have the top of the lever level, or, if anything, sloping slightly upward towards its outer end, thus preventing this tendency of the ball to work further out, and, by this means, avoid the use of the above devices, some of which may I think interfere with the free rising of the valve. As I have already written and sketched what I consider a most easily made and at the same time reliable method, I will here suggest a different one, namely—drilling axially, in the top of the valve stem, a hole not exceeding in diameter, say, one-quarter the diameter of the valve stem, and inserting in it a piece cut from the head end of a machine bolt to fit. If necessary file or grind some off of the top of the head of this bolt, leaving it a little higher at the centre than at the outer edges. The accompanying sketch is supposed to represent a sectional view with the hole in the stem bottomed out flat, as this would let the body of the bolt bear weight without jamming so tight as to be difficult to remove subsequently if this was desired.

In making the repair care should be taken to see that no chips or filings attach themselves to the valve stem or get a chance to work into any part of the valve mechanism, and this should be attended to before re-assembling the valve. It would not do to attempt this repair with the valve assembled. When firing up after making this or any safety valve repair, one should carefully watch both the steam gauge and the safety valve to see that they correspond as before.

With regard to accumulation of pressure after the safety valve lifts enough to let steam escape, there are rules which allow an accumulation of 7 to 10 per cent., but as a matter of personal opinion I do not like to see the pressure rise very much after the valve once lifts, and more especially so if the draft is at the time reduced to a minumun or nearly so. At any rate by the B.O.T. rule, which allows of an accumulation of ten per cent., the test is that in the presence of a person authorized or appointed by the Board, the boiler shall be under full steam and full firing for twenty minutes with feed and all stop valves closed. Obviously a valve amply large to permit of this with an accumulation of only 10 per cent. should allow but little accumulation in the case of a temporary shutdown of the engine and with the furnace draft then reduced as far as practicable.

In the event of a valve already installed proving itself inadequate by allowing too much of this accumulation, some one or more of the rules given in the beginning of this article may help toward deciding what size auxiliary valve (if any) is required.

In one or two cases I have known a valve to drizzle and blow some at 3 to 5 lbs. pressure, below that at which the valve actually lifted from its set, and in these cases proper regrinding put them so that there was no apparent accumulation after the valve began to blow, although to a bystander there would appear to have been while they were in their former leaky or worn condition. To the engineer, however, the cause of the apparent accumulation was self-evident. He would be quick to distinguish between an apparent accumulation due to a worn valve, and an actual accumulation due to small valve area, and would apply the proper remedy when circumstances permitted work on the valve.

HOW TO BLACKEN BOLT HEADS

JOHN H. BEDELL

(Copyright All Rights Reserved.)

Specially prepared lacquers can be obtained from supply houses for giving metal work for electrical switchboards a dull black finish. If such preparations are not available, dull black paints, which will serve in emergencies, can be obtained in ten-cent. or larger cans at most hardware stores or paint shops.

The following process has been used successfully for giving bright-finish steel cap bolt heads a dull black finish: First, heat the bolt to a dull red in a blow-torch flame, then dip it in asphaltum paint. Now burn the paint off with a blow-torch and rub it with a cloth while it is still warm. If the bolt is permitted to cool before it is rubbed with a cloth, the resulting finish will be glossy instead of dull.

The Cooper-Hewitt Electric Company, Hoboken, N.J., have issued an attractive calendar well illustrated with half-tone engravings showing installations of their lighting systems. This calendar shows installations in various classes of manufacturing establishments from machine shops to textile mills.

Supports for Wrought Iron Conduit

Many Circumstances Arise in Which the Ordinary Pipe Hanger or Clip Cannot be Used for Supporting Conduit Work—The Author Gives Some Practical Hints Which Help in the Erection of Conduit or Pipework

By E. A. HUGHES

(Copyright. All rights reserved)

IN planning industrial-plant wiring installations for electric light and power, the designer must frequently use, for supporting conduit runs, devices which cannot be obtained commercially. This is true particularly when the wiring is being installed in a building of structural steel construction. Where a concern erects considerable wiring, it is always advisable to insure minimum cost, to standardize a line of conduit supports. However, it may happen that the amount of wiring which is installed does not justify this procedure. Under such conditions the engineer must design his supports as he proceeds with the planning of the job. It is the intention to show in this article some supports which have been used, particularly in steel mill buildings, for sustaining conduit, and which experience demonstrates are entirely satisfactory.

Probably the fitting applied most frequently for supporting conduits is the

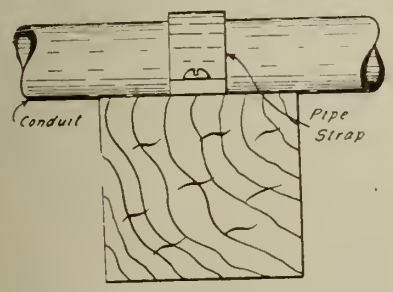


FIG. 1—CONDUIT FASTENED TO TIMBER BY A PIPE STRAP.

standard galvanized pressed-steel pipe strap. This can be obtained at the plumbers' supply houses for pipe of practically any commercial size. On

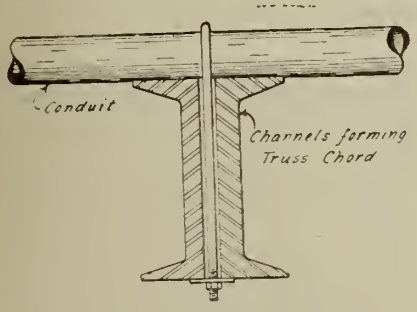

FIG. 2—CONDUIT CLAMPED TO CHANNEL BY MEANS OF V BOLT.

wooden surfaces, the strap, with the conduit clamped under, it can be attached with round-head wood screws, as shown in Fig. 1. Sometimes flat-head screws are used for this purpose, but they are not well adapted for it. Where a flat-head screw is applied, the flat part of the head of the screw will project above the surface of the metal of the pipe strap. It thus provides a place where dirt and dust can collect and upon which cloth or waste will catch if these materials are used for wiping off the conduit. When the conduit run is located where it will not be seen, this feature is of no importance, but close to the floor, or around the machines where the conduit may be wiped occasionally, it should be considered.

Where pipe straps are used to clamp conduit runs to the faces of steel columns, or to other members, small holes can be drilled in the members and then tapped for the accommodation of machine screws that will pass through the holes in the pipe strap. U bolts are very useful for clamping conduit runs to the chords or to other members of trusses, which a conduit run crosses. Figs. 2 and 3 show typical applications. Usually there is a space between the two members comprising the top or the bottom chord of a truss. This slot is the thickness of the gusset plate to which the members are riveted.

It is the practice of the fabrication plants to make these gusset plates as thin as is consistent with good design. Sometimes the slot is only 3-16 in. or ¼ in. wide. If such narrow slots are provided in the truss, it is not possible to get a U bolt big enough to have adequate strength through the slot. The U bolt for this purpose should be made of rod at least ¼ in. in diameter. A 3-16 in. rod can be used where the space available will not accommodate a larger one. However, experience has been that the wiremen, in tightening up the bolt on a 3-16 in. thread, will twist the rod asunder at a thread.

If the matter is considered prior to placing the order for roof trusses, arrangements can be made with the fabrication plant to provide a wide space, at least 11-16 in., between the steel members forming the truss chords. The bolts used in any space should be 1-16 in. in diameter smaller than the width of the space, to provide adequate clearance. A 5-8 in. bolt can be used in an 11-16 in. slot. A bolt of this size is much larger than is required for supporting conduit, but it is none too large for supporting steam and air pipe lines, heating and ventilating ducts and shaft hangers. It is seldom that a U bolt made from a rod larger than 3-8 in. is required for supporting conduit; 1-4 in. rod is more frequently used and is the best all-round size. As above noted, 3-16 in. rod is too small for best results.

Fig. 2 shows a line of conduit supported on the upper flanges of two channels comprising the lower chord of a truss. Space between the channels is ½ in. wide, and the U bolt is of ¼ in. stock. A punched washer is inserted under the nuts of the bolts, so that the corners of the nuts will not catch on the edges of the channel when the nuts are turned. Fig. 3 shows a similar arrangement wherein a conduit line is clamped to the upper edge of a truss chord composed of two angles. This arrangement provides a very secure support, because the relatively sharp edges of the angles dent into the conduit slightly, due to the pressure exerted in turning the nuts. The dents made by the angle edges, though usually deep

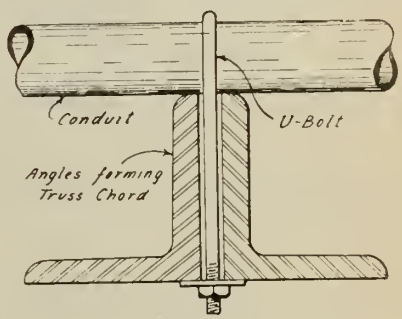

FIG. 3—DETAILS OF "U" BOLT FOR 2 IN. CONDUIT.

enough to prevent lateral movement of the conduit, are not deep enough to injure it appreciably. It is impossible to exert enough pressure by turning the

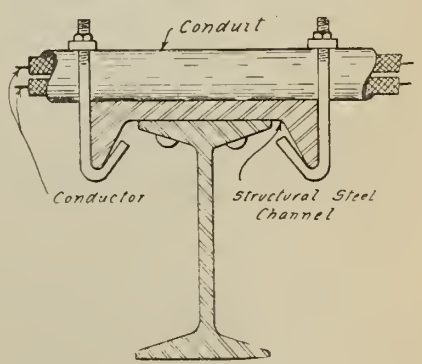

FIG. 4—CONDUITS CLAMPED BY HOOK BOLTS.

nuts of a ¼ in. U bolt to crush the conduit. The ¼ in. rod will break at the threads before the conduit will crush.

Each angle is 6 in. x 4 in. x ⅜ in. section. The U bolt is bent from ¼ in. stock. When making the U bolts, the

ends must be threaded before the ends are bent into a U form, because after it is bent there is not sufficient clearance for turning the die for threading. U bolts can be made very quickly from ¼ in. rod by cutting the stock cold for the required number, and then threading the ends, and bending the threaded rods around a piece of the conduit of the required size. The rods can be bent cold. Punched washers are provided in Fig. 3

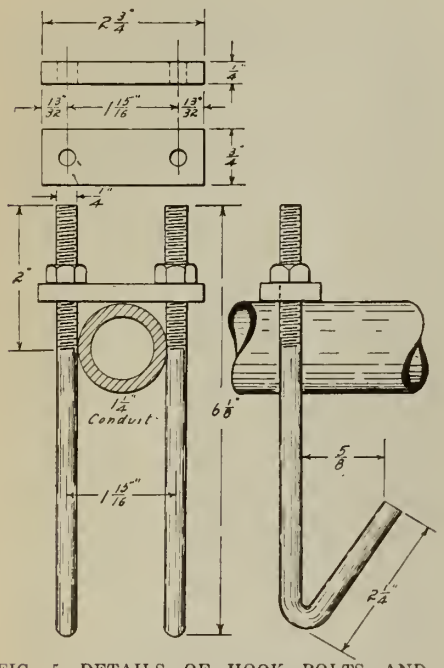

FIG. 5—DETAILS OF HOOK BOLTS AND STRAP FOR 1¼" CONDUIT.

to prevent the corners of the nuts from catching on the edges of the angle when the nuts are turned.

Sometimes it is necessary to attach a conduit run to a girder composed of a channel and I beam, as shown in Fig. 4. Two hook bolts and a strap similar to those detailed in Fig. 5 for 1¼ in. conduit can be used for making the attachment. The bolts are bent from ¼ in. rod. The hook on each bolt can be formed by bending it over the flange of a channel, or an I beam of suitable section. The pitch or slant of the flanges on all standard I beams and channels is 6:1, and the hook on the end of the bolt can be bent accordingly, if a section suitable for a bending form is not available. The strap for use with each pair of hook bolts can be cut cold with a shear from bar, and the 5-16 in. holes in each strap can be punched rather than drilled.

A method of supporting a conduit up to the face of a column is outlined in Fig. 6. In a location where neatness is essential, it is much better to support a conduit run up a column like that of Fig. 6, with pipe straps held by round-head machine screws turned into tapped holes in the column, than with the clamp illustrated. However, where a great many attachments have to be made to column faces, and where they are in non-conspicuous locations, it is usually cheaper to make up a clamp similar to that of Fig. 6 in the shop and send it out to the jobs, than it is to drill and tap screw holes in the columns for the pipe straps.

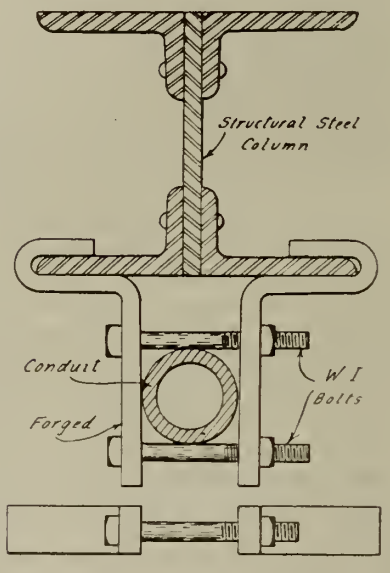

FIG. 6—CLAMP SUPPORTING CONDUIT ON FACE OF COLUMN.

NEWLY-DISCOVERED PRODUCT

Everybody knows that the Zeppelins failed in the war owing to their vulnerability, due to their being filled with hydrogen. German chemists failed to find a substitute, but the British Admiralty has found one and has arranged for its production in large quantities. The Canadian Mission, whose offices are in Regent Street, state that helium has been found in Canada. Next to hydrogen, this is the lightest known gas. Helium is a most suitable filling for airship envelopes, in that it is non-inflammable and non-explosive, and, if desired, engines could be placed within the envelope and a smaller internal envelope could contain the gas. By its use it is possible to secure additional buoyancy by heating the gas, and this fact may possibly lead to considerable modification of air ship manoeuvres and navigation. The loss of gas from diffusion through envelope is less with helium than with hydrogen, but, on the other hand, the lifting power of helium is 10 per cent. less than that of hydrogen.

It became evident from preliminary investigations made by Sir Richard Threlfall, and from calculations submitted to him as to cost of production, manipulation, etc., that there was ground for believing that helium could be obtained in large quantities at a cost not prohibitive. Professor J. C. McLennan, of Toronto University, was invited by the Board of Inventions of the Admiralty in 1915 to determine the helium content of the supplies of natural gas within the Empire, to carry out a series of experiments with the helium available, and also to work out all technical details regarding the production on a large scale of helium and the purification of such supplies as might be secured. In the course of investigations it was found that large quantities of helium were available in the natural gas in Ontario and Western Canada, which could be produced at the cost of 1s. per cubic foot. In the summer of 1917, when the United States had decided to enter the war, and when the investigations of Professor McLennan were well under way, proposals were made to the authorities in the United States to co-operate by developing the supplies of helium available in the United States. These proposals were made on behalf of the Admiralty, through the Board of Inventions and Research, by Sir Ernest Rutherford, and a special commission consisting of Commander Bridge, Lieut.-Commander Lowcock, and Professor John Slatterly. The proposed co-operation was agreed, and large orders were at once given by the American authorities for machinery and plant. By July, 1918, the production of helium in moderate quantities was accomplished, and from that time onward the possibility of securing large supplies was assured.

At the same time, all the practical details of the production of helium-borne airships and their navigation were developed by the Airship Production section of the navy. Also under the direction of Professor McLennan, steps were taken to erect and equip a station for purifying the helium which might become contaminated in service. Experiments were also made with the object of developing the possible technical and scientific use of helium. The progress made by the time the armistice was declared warrants the opinion that at the end of another year large quantities of helium would have been produced in Canada at low cost, helium-filled airships would have been in service, and great strides would have been made in exploiting the technical and scientific uses of the gas. This is a wonderful achievement—an achievement which, before the war, would have been scouted as impossible even by scientific men. That it has been accomplished is due to the enterprise of the Admiralty and the expert knowledge and skill of a Canadian scientist and his colleagues.

The Simonds Manufacturing Company, Pittsburgh, Mass., have issued a publication on Simonds' products in the war. This is a very attractive and interesting publication dealing with the part the Simonds Company played in the winning of the war. The development of the American Steel Helmet was in large measure due to the activities of this firm and the manufacturing of armor plate for machine guns and other purposes. The steel used by this firm was found to be of extremely high quality.

The Whitman & Barnes Manufacturing Company, Akron, Ohio, have issued Number 91, descriptive of twist drills, reamers, special drop forgings, and other manufactured products.

The Energy Liberated by Boiler Explosions

The Boiler is Potentially as Full of Mischief as an Ammunition Dump and May Cause as Much Destruction. This Article Deals With the Amount of Energy Liberated and the Sequence of Events

By T. H. FENNER, Editor Marine Engineering

A QUESTION was recently asked in the Question Box of POWER HOUSE, relative to what is the sequence of events during a boiler explosion.

The whole catastrophe takes place in too short a time to permit of any detailed observation, and the unfortunate party in close proximity rarely has the opportunity of relating his impressions, at least, on earth. However, our knowledge of the forces involved gives us a pretty fair idea of what happens, and thus we can explain the phenomenon with some degree of accuracy.

In the first place, it must be clear to everyone that the rupture precedes the explosion, and is the cause of it. The explosion does not cause the rupture.

Let us consider for a moment just what we have in the way of potential energy confined in the interior of the boiler.

Suppose we have a 72-inch diameter horizontal return tube boiler, with 72 four-inch tubes, and 18 feet in length. The cubic capacity of the interior, deducting the space occupied by the tubes, will be roughly 395 cubic feet. The space above the water level, assuming the water to be carried at half glass, a fair working height will be represented by a segment 14 inches high, and the full length of the boiler. This will be equal to a volume of 69 cubic feet.

We have, therefore, a volume of water of 326 cubic feet, and as a cubic foot of water weighs 62.5 lbs., the total weight of water contained in the water space will be 20 375 lbs. We will say, roughly, 20,000 lbs., to keep the members in round figures. Suppose for pressure we assume 1250 lbs. gauge.

In order to arrive at a computation of the energy contained in the boiler we must study the subject of latent heat a little.

Whenever the physical state of a body be changed, such as a liquid changing to a gas, or a gas to a liquid, the change is accompanied by the addition or subtraction of heat, which is energy. For instance, when the liquid ammonia in a refrigerating machine is passed through the expansion valve from the condensor to the cooler, in order to change from a liquid to a gas, it extracts the necessary heat from the brine coils. This heat is not to be confused with temperature, which is a different thing. In the same way, water in changing into steam extracts the necessary heat from the fuel. In changing from steam back to water the heat is given up, either in doing work on a piston, or in heating the surrounding air, or is carried off by condensing water. By the first law of Thermo dynamics, "Heat and mechanical energy are mutually convertible, and heat requires for its production, and produces by its disappearance, a definite number of units of work for each Thermal unit.

The British Thermal unit is the amount of heat required to raise one pound of water one degree in temperature, and is equal to 778 foot pounds of work.

The heat applied to water to raise its temperature is called sensible heat, as it is apparent by the raising of the temperature, as shown by the thermometer. The heat applied to water to change it from water at 212° to steam at 212° is called latent heat. That is, the heat has been supplied to the water to change its state without raising its temperature, but has increased its energy by a definite number of foot pounds, corresponding to 778 foot pounds for every unit of heat added.

To change water at atmospheric pressure to steam at atmospheric pressure and 212° temperature, requires the addition of 966 units of heat, and the total heat contained in the water will be 1,146 Thermal units.

As the pressure is raised the total heat is raised, but the relation between latent and sensible heat does not remain the same. The amount of latent heat decreases and the temperature increases, till at 125 lbs. gauge the total heat is 1189.5, the latent heat is 865.5, and the temperature 352.8, the quantity of heat above 32° to raise the water to the new boiling point being 324°, instead of 180° at the atmospheric boiling point of 212°. The total heat is affected slightly by the specific heat of water, which varies with temperature and pressure.

Specific heat, like specific gravity, is used to compare properties of different liquids with water. Water at 62° has a specific heat of one ,and above and below that the specific heat increases. For instance, one unit of heat is required to raise one unit of water one unit of temperature from 62° to 63° F., while to raise the same unit of water one unit of temperature from 32° to 33° would take 1.0094 units of heat, and from 320° to 321° would require 1.0285 units of heat.

To come back to our boiler. We have a quantity of water and a quantity of steam contained in one vessel.

The steam occupies 69 cubic feet, and the weight of a cubic foot of steam at 125 lbs. gauge is .316338 lbs. Multiplying this figure by 69 gives us 21.82 lbs.

Total heat of steam at 125 lbs. gauge pressure is 1189.55 B.t.u. and this figure multiplied by 21.82 represents the total heat in the steam. This product is 25955.98, say, 25956 B.t.u.

In the water space of the boiler we have 20,000 pounds of water at a temperature of 352.82, corresponding to a total amount of heat above 32° of 324.003. (The discrepancy shown by this latter figure, as compared to the result of subtracting 32 from 352.8? which would give 320.82 instead of 324.003, is due to taking into account specific heat.)

324.003 x 20,000 = 6480060 B.t.u.'s in the water.

Now, supposing a plate gives way, what occurs? The water in the boiler is suddenly reduced from a pressure of 125 lbs. to atmospheric pressure, and the steam in the boiler likewise. Now, at atmospheric pressure the total heat in steam is only 1,146 B.t.u.

We have available in the boiler a total quantity of heat amounting to 25,956 B.t.u. contained in the steam, and 6,480,060 contained in the water, altogether 6,506,016 B.t.u.

The water being released of its confining pressure, will flash into steam, absorbing heat to do so. There is sufficient heat present to change 5,655 lbs. water into steam at atmospheric pressure, and as steam at atmospheric pressure occupies a volume 1,646 times that of the water it is generated from, the whole of this energy will be available for removing obstacles to its expansion. Assuming that only 5,000 lbs. of water changes into steam, we have a total heat energy of 5,000 x 1146.6 = 5,733,000 B.t.u. Each of these is equivalent to 778 foot lbs. energy. Therefore, we have a force of 5,733,000 x 778 = 4,460,274,000 foot lbs. Dividing by 2,000 for foot tons we get 2,230,137 foot tons.

Allowing the force to be in operation ten seconds, the horse power developed would be 810,834.

Supposing the boiler weighed 18,000 lbs. and the water not vaporized weighs roughly, 14.000 lbs., say a total weight of 32,000 pounds. If the total energy could be concentrated on raising this weight it would be sufficient to lift it a height of 26 miles.

However, the energy is dissipated in other ways. Part of it is utilized in tearing the plates apart, and again there is an enormous air resistance against the irregular shaped masses of steel tending to stay their progress.

Suppose it started at an initial velocity of 3,000 ft. per sec., as a projectile is fired from a long-range gun, leaving the ground at an angle of say 60°. Then the range would be about 80 miles, equal to the best efforts of our friends, the enemy.

Therefore, in the light of the foregoing, avoid explosions.

THE WATER POWER RESOURCES OF AUSTRALIA AND THEIR POSSIBILITIES

By SIR DOUGLAS MAWSON, in the "Commonwealth Engineer."

THE material greatness of a nation is measured by its output of energy. In this, human effort is supplemented and may be greatly augmented by the application of the energy available from coal and water-power. Lands blessed with such natural stores of energy are endowed with an enviable asset. The jealous eyes of less fortunate neighbors are certain to be turned towards them, so it behooves the Governments concerned not only to develop such resources as far as practicable, but to safeguard the proceeds in the interests of the citizens themselves.

With a view to the conservation of the national assets, a policy should be adopted of utilising water-power in preference to coal wherever economically possible; for the former remains undiminished by its application, whereas the latter is steadily used up. Even though the existing coal measures promise to meet the demand for a very long time to come, the winning of coal is likely to become more expensive as time goes on, if only for the reason that the wider and more accessible seams are worked out first.

Water-power has come into great prominence during the last two decades, and more recently its advantage over coal as a source of power for certain special industrial purposes has been clearly demonstrated. Moreover, as wages, which constitute the major portion of the cost of coal, are steadily and surely rising, the economic conditions of the future will still further favor water-power and tend to limit the employment of coal. Statistics show that in the United Kingdom, prior to the outbreak of war, wages amounted to 63 per cent. of the total cost of coal at the pit mouth; this was slightly exceeded in the U.S.A., where the figure was 69 per cent. So there is every reason to expect that year by year the price of coal will rise. In this connection somebody has predicted that after the disappearance of sailing craft from the ocean traffic, an era will some day eventuate when, on account of the high cost of coal, wind propulsion will once more come into vogue, and all vessels save mail steamers will voyage under sail.

The case for water-power on its own merits is certainly a strong one. A survey of the hydraulic possibilities of a country is quite as important as the estimation of coal resources. The fuel reserves of the British Empire are known, but there is no such information existing regarding the available water-power. In connection with after-war reconstruction a move has been made to ascertain what are the possibilities of this nature within the Empire. Already an introductory report has been issued by a water-power committee of the conjoint board of scientific societies, Burlington House, London, the object being to urge colonial Governments to take up the subject with a view both to the development of such potential energy and to the passage of controlling legislation. In the report an endeavor has been made to indicate roughly the contribution to be expected from each part of the Empire; the aggregate is shown to be not less than 50,000,000 e.h.p. In the case of Australasia the data available is very fragmentary, so that Professor T. W. E. David and myself, who were called upon to furnish the figures, had to make the best of the meagre information published to date. However, embodying such definite values as have been published, and for unsurveyed areas adopting figures suggested by an examination of the rainfall and topographical charts, certain rough totals were arrived at which are at least suggestive of the possibilities. The actual figures published are as follows:—

Australia	1,000,000
Tasmania	400,000
Papua	8,500,000
New Zealand	3,822,000

Great possibilities are indicated for Papua, prospects equally shared in Dutch New Guinea and the former German section. The Commonwealth Government would do well to investigate Papua and ascertain by hydraulic survey to what extent water-power is actually available. In the case of New Zealand, a complete hydraulic report is available, published by the Government works department. There, a record of available schemes is set forth aggregating 3,822,000 b.h.p. In this respect, therefore, New Zealand is one of the most richly endowed territories in the world, being at the rate of 37 h.p. per square mile of area. One single scheme, that proposed for the shores of George Sound, is planned to yield 750,000 b.h.p.

The great strides made in electrochemistry during recent years have widened the outlook for hydro-electric developments, but the latest turn in this connection, namely the fixation of nitrogen from the atmosphere, has revolutionized the economic possibilities. For this purpose, in Norway alone, over 400,000 b.h.p. is now absorbed. The world's annual consumption of nitrogen in its various combinations is about 750,000 tons, and the demand for nitrogenous fertilizers is growing yearly. There is no doubt that a large proportion of this power in Australasia can be realized at a sufficiently low figure to allow of competition in the world's markets. A few years ago, either in Norway or America, £20 per kw. installed would have been regarded as a high figure, but now all the cheaply developed sites have been taken up and £26 per kw. installed is regarded as a moderate figure. New Zealand, especially with its wealth of water-power, should have a great manufacturing future, and might well specialize in nitrogen fixation. To illustrate the importance of its application in this respect it is only necessary to refer to the scheme indicated for George Sound. There, something like 750,000 kw. is available at the foreshore which could be employed converting the nitrogen of the atmosphere into ammonium or other forms ready for shipment. A 750,000 kw. plant is capable of producing annually by the arc process 416.250 tons of concentrated nitric acid, equivalent to 92,250 tons of combined nitrogen, or by the cyanide process 1,635,000 tons of cyanide equivalent to 327,000 tons of nitrogen. Were the electrical power to be generated by steam from coal-fired boilers, to produce the same result 4,875,000 tons of good coal would need to be consumed annually.

AN EMPLOYER'S SCHEME

By L. P.

Regarding the coal and gas shortage, the head of a well-known cutlery concern has posted up in his works the following notice: "In regard to the coal and gas shortage, it is necessary for workpeople to do all in their power to economize. This is not on any account because of the increased prices of these commodities, but because, at the moment, it is a national necessity. If economy is not used in coal and gas it is very probable before the end of the coming winter, the hours of work will be restricted owing to the lack of light and heat. To encourage the workpeople to put forward every effort to save coal and gas wherever possible, I am making the following offer: For every ton of coal saved during the coming winter as compared with the amount used last winter, dating from Sept. 1 to March 31, I will pay the sum of one pound. For all the gas saved in comparison with the corresponding period of last year I will pay the equivalent amount based on the present cost of gas in comparison with the cost last year. The money will be paid into the Works Club funds, and all workpeoeple, whether male or female, must equally divide. It is therefore in the interest of every person to do their utmost to save and also to see that other people do not waste." If such an example were followed by other industrial establishments we should soon have an army of coal and gas-saving enthusiasts.

Electric Furnaces.— The Electric Furnace Construction Co., Finance Building, Philadelphia, reports a repeat order from the Ford Motor Co., for a "Greaves-Etchells" electric furnace installation. The initial furnace was installed last year and it is reported that it has given extremely good results. In England further orders have been received for furnaces from Woodward, Gatty, Saunt & Co., Ltd., Birmingham, and G. & J. Weir, of Glasgow.

INDUSTRIAL USE OF GAS MASKS

During the last year the Bureau of Mines, Department of Interior, Washington, has received many inquiries regarding the use of army gas masks in the industries for protection against poisonous and irritating gases. These inquiries show a general belief on the part of the public that this type of mask will protect the wearer under all conditions against any gas whatsoever, even in absolutely irrespirable air to the exclusion of the more cumbersome mine rescue breathing apparatus. This erroneous belief will no doubt be further confirmed by millions of discharged soldiers who have been trained in the use of the gas mask and have been taught that it gives them absolute protection against all gases used in warfare or likely to be used. These men will not realize that out in the open air of the battlefield the percentage of gas in the air can never be anywhere near as large as may occur in the confined spaces of a factory operation. A mask may afford complete protection under outdoor conditions, and break down at once when used indoors where a gas container has burst and filled the room with a greater concentration of gas. It must also be remembered that the absorbents in the army respirator, which filter out the poisonous gas, are specially designed for the gases used in warfare, and as a matter of fact do not protect against the more common industrial gases as, for example, illuminating, natural, producer and blast furnace gas.

The army gas mask never should be used in mines because of the uncertainty there is of the kinds and amounts of gases in the atmosphere and liability of insufficient oxygen to support life.

In view of these limitations of the army gas mask, which, if not realized, will lead to serious acidents and fatalities, the Bureau of Mines is issuing this brief statement of the industrial use and limitations of the several dust respirators, gas masks, and oxygen breathing apparatus.

Dust Respirators

Protection from dust and liquid mists is obtained by the use of a simple dust respirator, which removes these particles by means of a filter of moist sponge, cotton, or wool pad, porous paper, or even a very fine mesh metallic gauze. The respirator may enclose the mouth and nose only, or it may be combined with a face mask containing eye pieces if the eyes also must be protected. The simple "pig snout" respirator, containing a moist sponge, has been on the market for years. It is highly uncomfortable to wear, rather insufficient for removing fine dust, and most workmen prefer to tie a large handkerchief over their nose and mouth. Some improvement has been made in recent years, but on the whole a really efficient and comfortable dust respirator that workmen will wear continuously is yet to be devised. On account of the urgent need of such a device for safeguarding the health of workmen in the mining and metallurgical industries, the Bureau of Mines has undertaken a study of dust respirators with a view to seeing that as satisfactory a model as possible is available to these industries.

Army Gas Mask

The army gas mask consists of a face piece of rubber and cloth fabric, containing eye pieces and connected by means of a flexible rubber tube to a canister containing charcoal and soda-lime for filtering out the poisonous gas from the inhaled air. The canister is supported in a knapsack slung from the neck.

The army gas mask is by no means the unusual protective appliance that it is popularly believed. It does not afford universal protection against all gases, nor can it ever be used safely in low oxygen atmospheres. It furnishes no oxygen to the wearer and can only remove comparatively small percentages of poisonous gas from inhaled air, usually less than 1 or 2 per cent. Higher percentages will immediately penetrate the canister and "gas" the wearer. The standard army gas mask will furnish protection against percentages not exceeding two per cent. of the following gases in air: Sulphur dioxide, hydrogen sulphide, chlorine, carbon bisulphide, nitrogen peroxide, aniline vapor, benzyl bromide, benzyl chloride, chloracetone, chlorpicrin, hydrogen chloride, phosgene, sulphur chlorides, xylyl bromide, stannic chloride, titanium tetrachloride, and silicon tetrachloride.

It will be seen from the above that the field of usefulness of the army mask is confined to certain of the chemical industries, around smelters and roasters, where sulphur fumes are given off and in the industries using chlorine and bleaching powder. The army canister also contains cotton filter pads, which remove irritating and poisonous dusts, which increases its usefulness around smelters where sulphur and arsenic fumes must be removed.

The army mask furnishes no protection whatever against carbon monoxide. This is the poisonous constituent of blast furnace, producer and illuminating gases, and of mine gases after fires and explosions in coal mines. Carbon monoxide is also likely to be present in ordinary fire-fighting conditions met by fire departments. Moreover, in all of these cases there is likely to be a deficiency of oxygen. Therefore, for adequate protection against these conditions the oxygen-breathing apparatus must be used, and reliance on the army mask may be fatal.

The Bureau of Mines is working on a carbon monoxide mask and hopes to develop one that may be used in the future for low concentrations of this gas, but such a mask is not now available.

Ammonia is another gas that will penetrate the standard army canister. However, a special chemical may be placed in the army canister which will adapt it for use around refrigerating plants.

Oxygen-Breathing Apparatus

The self-contained oxygen-breathing apparatus can never be displaced by the gas mask for use in atmospheres deficient in oxygen. Such atmospheres are encountered in mine rescue work, in gas mains, blast furnace stoves, gasoline tanks, etc. Aside from the lack of oxygen, carbon monoxide is also present, for protection against which the army mask is useless.

The oxygen-breathing apparatus must also be used instead of the army gas mask wherever there are large quantities of irrespirable or poisonous gases, as for example, in entering a gasoline tank containing some residual liquid, or similar tanks, towers, and other closed spaces. The concentration of vapors produced by volatile liquids in closed containers is too high to be entirely removed by gas mask absorbents. The only recourse in such cases is a self-contained appliance in which the wearer does not breathe any of the irrespirable atmosphere.

Importance of Expert Advice on Protective Breathing Appliances

Owing to the many factors entering into the use of protective respiratory appliances the importance of competent advice on the selection and use of such appliances cannot be over-estimated. The fact that the army and navy used gas masks has been widely disseminated, and its significance is likely to be misunderstood, especially by men who have had some training in their use. It also should be made known that both the army and navy used the oxygen-breathing apparatus in its appropriate place.

In connection with the Bureau of Mines work of safeguarding the health of miners and workmen in the metallurgical industries, a general investigation of respirators, gas masks and breathing appliances is being undertaken at the Pittsburgh Experiment Station of the Bureau. This research will be conducted by experienced chemists and engineers who had charge of gas mask research in the Bureau's war gas investigations and subsequently in the Research Division of the Chemical Warfare Service, U.S.A.

The industrial respirator investigation will include:

(1) Advice on the suitability of the standard army gas mask for use in various industrial gases.

(2) Approval of industrial gas masks and respirators, when properly submitted to the Bureau by the manufacturer in accordance with a schedule to be announced later.

(3) Instruction of workmen at plants in the use of masks and respirators in a manner similar to that now being given by the Bureau in the use of oxygen-breathing apparatus.

Ackersand High Head Electric Plant

A Description of a Swiss Power Plant Using Water at the High Head of 2,000 Feet and Generating 27,000 Horsepower

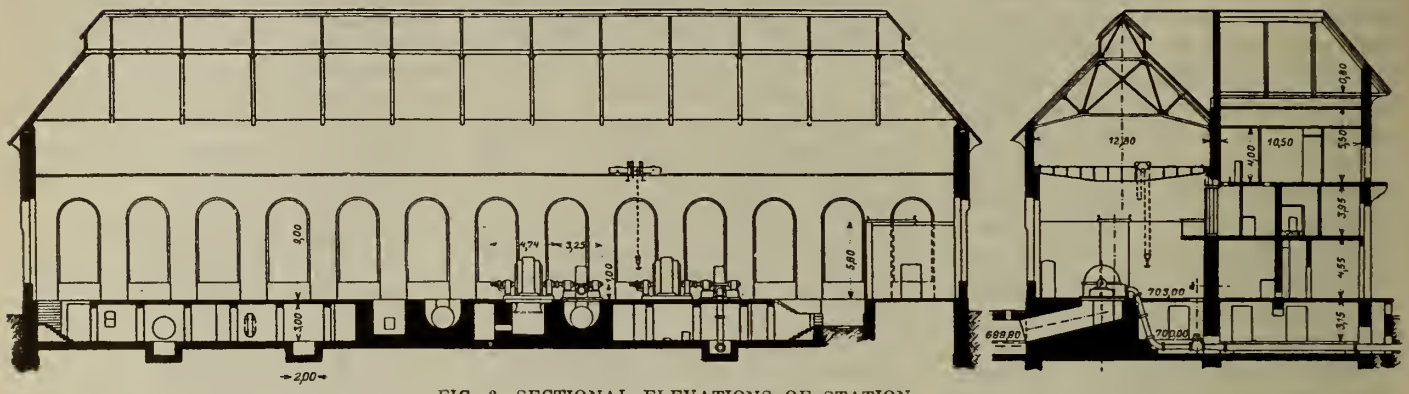

FIG. 3—SECTIONAL ELEVATIONS OF STATION.

THE accompanying illustrations, Figs. 1 and 2, and drawings, Figs. 3, 4 and 5, show the Pelton water wheels of 5,550 horsepower and the details of construction of the Hydro-Electric equipment of the Ackersand power plant. The original equipment of this central power station of the A. G. Elektrizitatswerk Lonza, located on the Zermatter and the Saaser Visp, was designed for a capacity of 27,000 horse power. The turbines were built by the Societe an. des Ateliers, Piccard, Pictet & Cie, of Geneva, Switzerland. These Pelton turbines operate under the enormous head of 700 meters, or over 2,000 feet. The speed of the turbine is 500 revolutions per minute. Each turbine is directly coupled to a 3-phase alternating current generator of 5,100 K.V.A. capacity, supplying a current of 15,500 volts pressure.

A 25-ton traveling crane on the Hydro-Electric station served to handle the turbine and generator parts during installation and repairs.

These hydraulic turbines of the Pelton type take 750 liters of water per second, and the regulation is automatic in operation with provision for hand regulation as well. The power is transmitted a distance of 6 kilometers to factories at Visp; also for electric heating and lighting service.

The intake is located at 1,400 meters above sea level, with a drop of 700 meters at the power house to 700 meters above sea level at the turbines. The upper portions of these penstocks were constructed by the Atelier de Constructions Mechaniques de Vevey, and the lower portion by J. P. Piedboeuf and Co. These lower sections of the penstocks are of great strength, the thickness varying from 13 millimeters to 30.5 millimeters.

The power house was designed by Architect M. Burgener of Siders and is a most artistic structure, extremely pleasing to the eye, yet its utility is unquestioned. The building is 66 meters long and 12 meters wide, with a tower 20 meters in height. The original plant provided for 5 units of 5,500 horse power as indicated in the drawing, Fig. 3, the turbines being of the horizontal Pelton construction, shown in the photograph, Fig. 2, and drawing, Fig. 4, and the automatic regulating mechanism of the type noted in drawing, Fig. 5. The turbine water wheels were constructed of Siemens-Martin steel, 280 millimeters in diameter, operating with automatic oil bearings. It is stated that this plant has given excellent service, and has been of great value in the industrial development of the surrounding country.

CONCRETE HOUSES FOR ENGLAND

Proposal For Speeding Up Buildings—Rental About $2 Per Week

LONDON, ENG.—A new method of reinforced concrete construction under the Government housing scheme has been designed to facilitate the erection of houses, and is now under consideration by the local and municipal authorities in the United Kingdom.

The system is said to be similar to that adopted for housing the American troops in France, and has been patented under the title of the "Lightning Construction System." Its superiority lies in the method of moulding the slabs. This is done on the actual site in portable

FIG. 1—TURBINE WITH DOUBLE REGULATION IN FRONT. IN THE BACKGROUND, TURBINE WITH HAND REGULATION AND AUTOMATIC REGULATION OF THE JETS.

FIG. 2—WHEEL WITH UPPER CASING REMOVED.

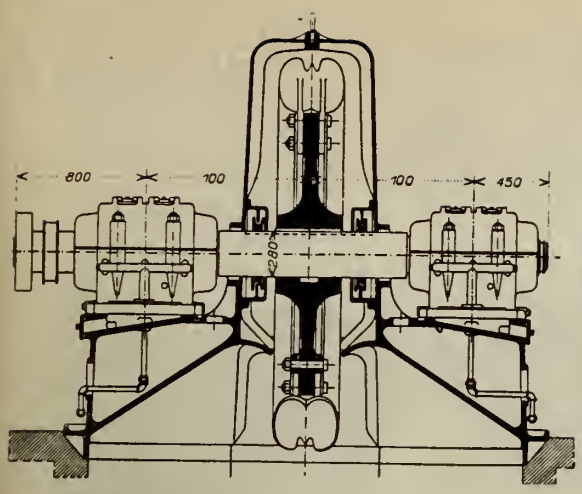

FIG. 6.

moulds. It is claimed that a block of three five-roomed houses can be built by twelve men in three days, using unskilled labor under skilled direction.

It is estimated that such houses when completed will cost the British public about £390 per house, or £415 including the cost of land with twelve houses to the acre. The houses would let at about $2 a week, according to local rates. The buildings will include the latest modern improvements. such as central heating.

Ball Bearing Manufacturers Combine.—Of interest to all users of bearings is the just announced reorganization, effective May first, whereby the products of The Hess-Bright Manufacturing Company, the SKF Ball Bearing Company, the Atlas Ball Company, and the Hubbard Machine Company will be sold through one central organization. The new company, under the name of SKF Industries, Inc. will thereby be able to offer a comprehensive line of ball bearings, including the Hess-Bright deep-groove type, SKF self-aligning radial and thrust bearings and ball bearing pillow-blocks and shafting hangers. Through the medium of its engineering organization, backed up by a well equipped laboratory, the new company will be able to place at the service of bearing users the knowledge gained in many years of anti-friction bearings of all kinds. On request, manufacturers' problems will be analyzed in detail and that type of bearing recommended which (independent of sales considerations) is best suited to the conditions met. In addition the laboratory staff will carry on research studies affecting anti-friction bearing design and application. The new company—SKF Industries, Inc.—will be under the direction of B. G. Prytz, President, W. L. Batt, Vice-President, J. P. Walsh, Comptroller, and S. B. Taylor, Sales Manager. The principal office will be at 165 Broadway, New York City, with branches at Boston, Philadelphia, Atlanta, Buffalo. Cleveland, Detroit, Cincinnati, Chicago and San Francisco.

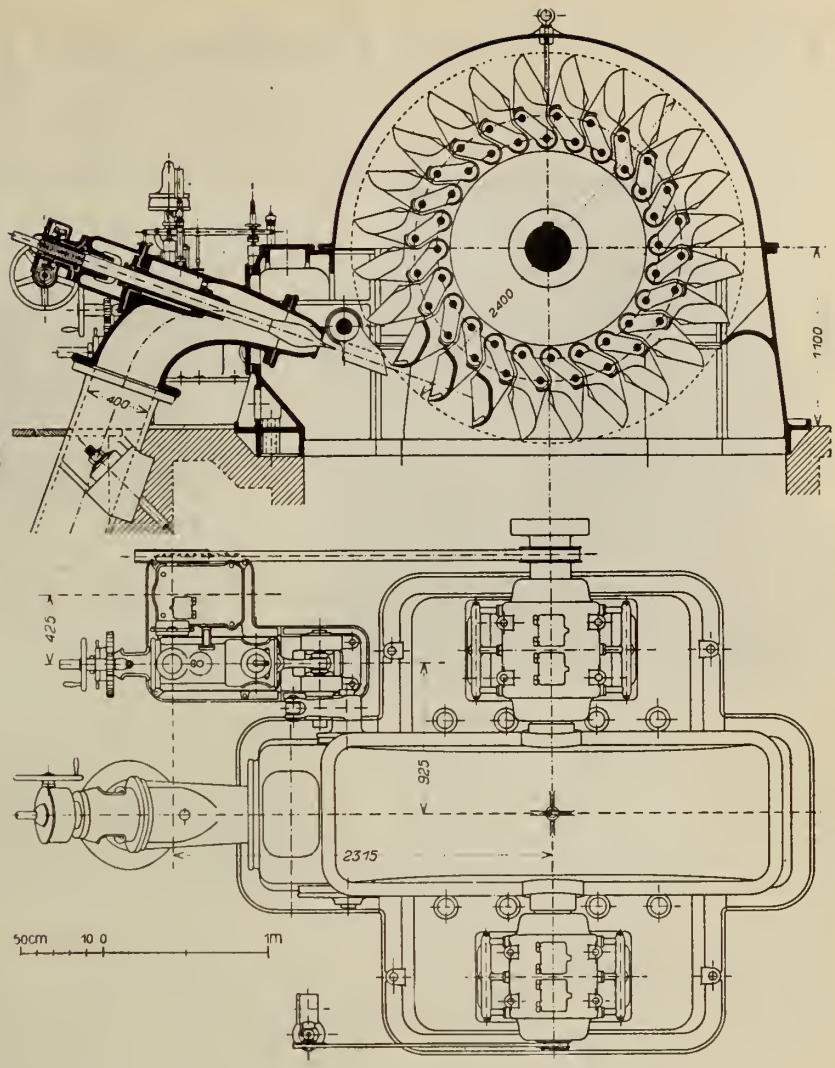

FIG. 4.

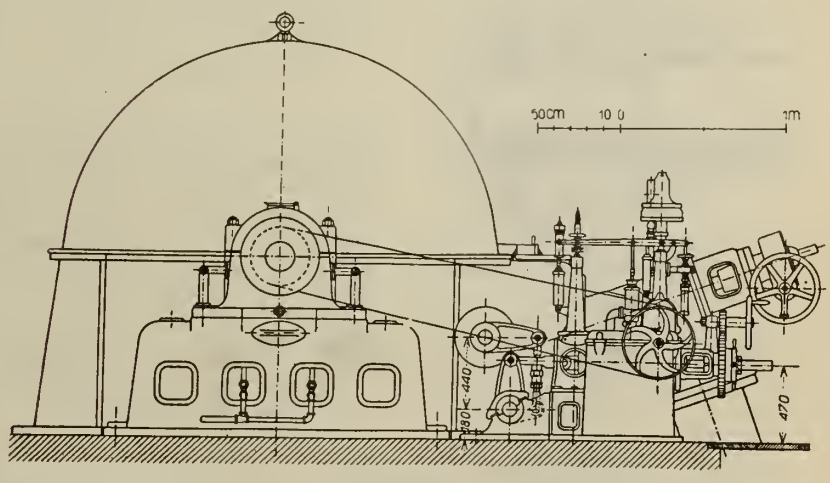

FIG. 5.

Buy Coal Now.—The Canadian Manufacturers' Association are sending out the following circular in regard to bituminous coal: As in the past two years, we again urge our members, in order to avoid congestion at the frontier in the fall and winter, to put in their season's requirements of bituminous coal in the summer months. Another factor which points to the wisdom of early action is that, as a result of shortage in the labor supply, production of bituminous mines shows a marked falling off. They are now running about 7,000,000 tons per week, as compared with 12,000,000 tons per week during the war. This condition leads to the belief that production is less than concurrent consumption, the difference being accounted for by the use of reserve stocks, accumulated at the instance of fuel administrations.

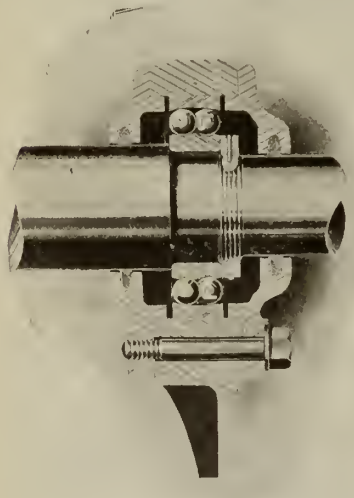
The Use of Ball Bearings for Electrical Machinery

Advantages of Ball Bearings—Enable the Builder to Use a Smaller Air Gap—Better Commutation Due to Greater Precision —Enhanced Efficiency Over Plain Bearing—Dimensions Smaller

By H. M. TRUMBULL

INDUSTRIAL operations are carried on for profit, and profit depends upon the difference between selling price and cost. This difference, due to the events of the past few years, has been steadily decreasing—especially in the manufacture of electrical machinery. For, on the one hand, the cost of all raw material has been advancing, as has also the cost of labor and the expense of marketing the product; on the other hand the manufacturers of electrical machinery, because of keen competition in this line, have not deemed it expedient to advance their selling prices in proportion to the increasing costs. The service rendered by electrical machinery produced by the various manufacturers is so nearly identical that no one company has considered it wise to take the initiative in marked advance of selling price. Such conditions might soon prove disastrous and so each manufacturer has been endeavoring to incorporate in his design some material improvement which will net the customer a present and ultimate economy and induce him to pay an increased first cost.

Almost simultaneously many of the manufacturers have answered this question by incorporating ball bearings in the design of their standard equipment. No other single improvement has been made in the last five years which has increased the ruggedness and economy of motors as much as ball bearings. This improvement has proven to be a sales advantage and ball-bearing equipment, because of its strong sales appeal, puts motor selling on a more profitable plane.



MOUNTING ARRANGEMENT WITH BALL BEARING ON MOTOR SHAFT.

For a number of years the desirability of using ball bearings on electrical machinery has been the subject of discussion by engineering societies both in this country and in Europe, but now this question has been taken out of the realm of discussion and made a cold dollars-and-cents proposition.

Not only has the incorporation of ball bearings in motors and generators lessened the selling expense for the manufacturer and allowed him to charge a higher price, but it has also offered such economies to the user of these machines that the higher initial cost has been much over-balanced and additional profits made possible. In fact, progressive mill owners, mine superintendents and shop managers all over the country, who are facing the same problems of advanced costs of materials and labor, are forced to introduce better machinery and to grasp every opportunity for completing a manufacturing operation in less time and at a decreased expense, and so they are specifying ball-bearing equipment.

In order to obtain an idea of the advantages of the application of ball bearings to electrical machinery, a series of questions was recently submitted to motor-manufacturing engineers and users of ball bearings throughout the country. A careful analysis of the replies, giving the tests and experience of motor designers and users, shows the following advantages in favor of ball bearings.

Maintained Air Gap

Among the principal advantages of ball bearings on motors are their precision and freedom from wear. The bearing adjustment remaining constant keeps the rotor in the center of the magnetic field. This permits the motor manufacturer to employ air gaps with clearances so slight that they could not be considered on motors having any other type of bearing. On induction motors a close air gap is of vital importance in the improvement of the machine efficiency and the power-factor.

Chief among the difficulties with plain bearings is the fact that after a period of service the bearings wear down to an amount varying with the load and service conditions. If this wear continues it will finally permit the armature to touch the pole pieces with resulting trouble—perhaps a stripped armature.

In a ball bearing, hardened steel balls roll on hardened steel bearing races, thus rubbing friction is practically eliminated and accuracy is maintained.

On axle-driven generators used for railway car lighting, the bearings must maintain the air gap or a stripped armature results. Ball bearings have replaced plain bearings for this service almost entirely because of the greater dependability attained. Records of 200,000 car-miles, where ball-bearings are used, have become common in spite of the frequently excessive tension of the belt. The shock and distorting action on the shaft due to crossovers, switch frogs and uneven track, the snap of the generator belt when flying ballast is picked up and passes between the belt and pulley, all deflect the armature shaft. It is found that self-aligning ball bearings accept these shaft deflections without binding or wear.

DIEHL TYPE K ADJUSTABLE SPEED INTERPOLE MOTOR FOR OPERATING STEERING GEAR ON SUBMARINES.

Improved Commutation

On direct-current machines, the fact that ball-bearing heads are sealed so as to prevent the escape of lubricant keeps the commutator clean. Commutators are thus protected against a conducting "slop" of dust and oil, and good commutation is maintained.

Precision and durability of bearing setting also insure better accommodation.

Freedom from sparks from the commutator in flour mills, in coal mines, in textile mills, in woodworking plants, or wherever there is combustible dust, reduces the possible danger of ignition or explosion, thereby materially decreasing the fire and accident hazard.

Comparative Frequency

On motors in which the shaft is subject principally to rotating action (torque), bearing friction is a very small percentage of the motor losses. This is the case in direct-coupled units, centrifugal pumps, motor-generator sets, etc. The bearings carry but little, if anything, in excess of the weight of the rotor; therefore pressure between shaft and

bearing lining is inconsiderable and bearing friction is a minimum.

Where the motor shaft is subject to bending action, however, bearing friction becomes an important consideration. This is the case with belt and gear-drive motors. The bearings are subject to severe bending, pounding or shock strains, especially at the driving end. Ball bearings in these cases show a decided saving over plain bearings. This is due to the fact that in ball bearings the friction is practically constant over a wide range of pressures, and because rolling is substituted for the rubbing action of plain bearings.

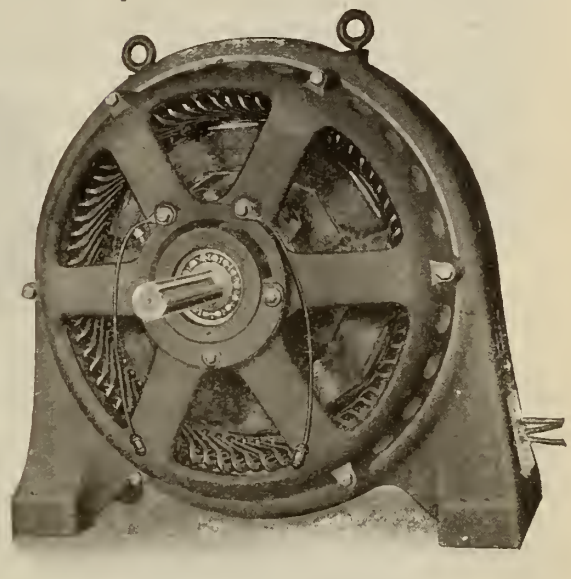
ROBBINS & MEYERS CO. THE END CAPS OF THE TWO RIGHT HAND MOTORS ARE REMOVED TO SHOW BEARINGS

Compactness

Compactness is required in conditions usually found in general industrial applications for induction and direct-current motors. To get this feature of compactness, motor manufacturers develop the greatest possible horsepower from a given size of motor frame. This reduced size per horsepower capacity gives the greatest driving power in limited space conditions.

The length of the motor bearings affects the question of compactness to an important degree.

Babbitt bearings are usually designed with the box length two and one-half to three times the diameter of the shaft which they support. Contrasted with this, the length of ball bearings along the shaft usually is not over one-third of the shaft diameter. Surrounding the ball bearing is the lubricating chamber, which at its outside limits is one-half to one-third shorter along the shaft than the plain bearing for the same motor, with the result that the over-all length of motors can be reduced 10 to 27 per cent.



FAIRBANKS-MORSE MOTOR EQUIPPED WITH BALL BEARINGS.

by the employment of ball bearings.

Where a consideration of aisle room, floor space, machine arrangement, etc., is necessary, a ball-bearing motor goes a long way towards solving the problem, as shown in the following table:

PLAIN DIRECT-CURRENT MOTORS.

Size of Motor.	—Motor Length Over All— Sleeve-Bearing Motor. Inches.	Ball-bearing Motor. Inches.	Reduction in Length. Per Cent.
5	26⅛	23	12
6	26⅞	24¼	9.8

50	57⅛	42 13/16	25

Simplicity and Cleanliness

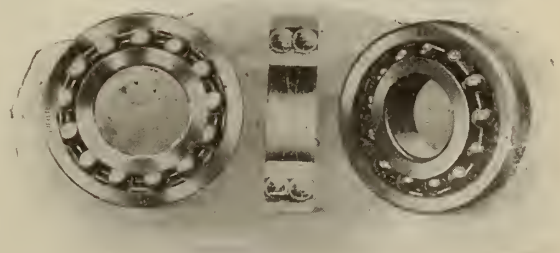
The use of ball bearings reduces the head construction to its simplest terms. Instead of oil rings, chains, wicks, waste packing or other devices which are required for plain-bearing motors, ball bearings require no oiling devices other than the ball bearing itself. Ball bearings are in themselves positive self-lubricators. Instead of necessitating frequent inspection of the bearings, renewal of the lubricant and possibly occasional rebabbitting, ball-bearing motors require no attention other than periodic lubrication—the length of time between inspections being from one week to six months, depending upon the service.

Ball-bearing motors are clean. The ball bearings are encased within bearing heads with sealing grooves on each side of the bearing, preventing the leakage of lubricant. With this protection, dripping or leaking of oil is eliminated and there is no danger of goods becoming soiled or contaminated with oil from this source.

Gear-Drive Motors

Where gear drive is used, ball bearings on electric motors are of particular advantage. In order that gears shall run smoothly and quietly, the proper distance between pinion and gear centers must be maintained. It is a fact that noisy, chattering gears may be caused by wear having taken place in the bearings supporting the gears. After long service

DISASSEMBLED VIEW OF MOTOR, SHOWING BALL BEARINGS.



SKF RADIAL BALL BEARING SHOWN IN NORMAL POSITION AND IN DEFLECTED POSITION.

with this type of drive, ball bearings show no appreciable wear and consequently the gears mesh properly, giving longer and better service.

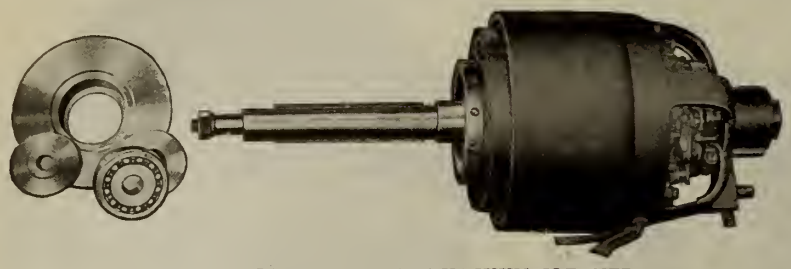
Plain bearings must be designed so that the pressures are well under the limit for the corresponding speed of the bearing. To reduce unit pressure in the bearing surfaces, it is necessary to increase the rubbing area. This may be done in either of two ways:

First, by increasing the journal length. This of course offers the disadvantage of increased floor space required by the motor, and where compactness is a desirable feature this is a serious handicap.

Second, by increasing the shaft diameter. Increasing the diameter increases in direct ratio the speed of the rubbing surfaces which should be kept as low as possible, because each increase of rubbing speed directly increases the likelihood of hot bearings. Larger shafts also mean heavier and more costly motors.

Whether, therefore, the bearing length or the shaft diameter be increased, the plain bearing is confronted with positive limitations.

Ball bearings are designed for high speed and heavy loads. The housings are short and the motor on which they are used may be made very compact. Because of the compact construction the distance between the bearing and pinion is reduced, hence the overhung load on the bearing is proportionately reduced.



BALL BEARING USED WITH VACUUM CLEANER.

Ball Bearings on Axle Generators

Ball bearings are now used almost exclusively on axle-driven generators for railways. A few years ago these machines were equipped with plain bearings. The service is so severe, however, and the attention which can be given is so small, that ball bearings have proved to be the only equipment that will "stand up."

The generators are exposed to snow and ice, heat, dirt and water, the jolts and shocks of passing crossovers and switches, and the continual jar of heavy truck suspension. These conditions all play havoc with plain generator bearings.

The testimony of a superintendent of inspection of one of the largest railroads in the country is eloquent with the advantages of ball bearings on these generators. He says, "The cost of generator maintenance has been reduced—on coaches, 66 per cent.; on diners, 46 per cent. We have never had a hot bearing, have not lost any fields or armatures, the inside of the generator is dry, and we have no trouble due to grounds or short circuits." This is typical service where self-aligning ball bearings are used.

The Lubrication Problem

Ball bearings offer the motor user one solution of his lubrication problem. The ball bearings are contained within simply constructed bearing-head brackets with liberal lubricant chambers which are sealed on both sides and by end caps. These end caps are fitted close to the motor shaft and are practically proof against leakage of lubricant, as well as the intrusion of moisture, dust, lint, grit or other foreign substances from without.

CHARGING MOTOR GENERATOR FOR STORAGE BATTERY WORK. EQUIPPED WITH BALL BEARINGS.

Ball bearings are positive self-lubricators. The ball spacer or retainer is of such construction that the bearings are open at the sides, thereby giving free

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Questions Asked In Last Issue

13. If your safety valve has been blowing off at 100 lbs. and now commences to blow at 80 lbs., what would you do to remedy the same, in the event of the steam gauge indicating 120 lbs. before the safety began to blow? What would you consider the possible cause, and what would you do to remedy the same? What action would you take?

14. If you were taking charge of a boiler where the safety valve steam gauge and water column had been taken off to prevent damage to same, and you were in doubt as to the correctness of the steam gauge, how would you set the safety valve when it was replaced on the boiler in order that it might blow off steam at 100 lbs. pressure, and in replacing the water column how would you set it at the correct height on the boiler?

15. Explain the construction and action of an expansion point as used on a main steam pipe. What omission in the construction of expansion joints would lead to serious accidents when steam is first applied?

16. Explain fully the construction and action of a safety valve spring-loaded pop. In what does it differ from the other ordinary spring-loaded valve? What is the advantage of the pop over the ordinary? How does the connecting of a long discharge pipe affect its working?

17. What is the meaning of factor of safety as applied to steam boilers? What is the real limit of the strength of a boiler? Explain the manners in which frequent variations of steam pressure affects the strength of boiler, and why?

18. Show by sketches and explain different ways of staying the segments of boiler heads above the tubes, stating the advantages and disadvantages of each method.

19. What is the difference between a direct current dynamo and an alternating current dynamo? In what way does a dynamo differ from an electric motor? Can a dynamo be run as a motor, or the motor as a dynamo?

20. If you were in charge of a steam plant where there was boiler power to spare, but the engine in its present condition was fully loaded, what would you do to increase the power of the engine in order to run extra machinery, assuming that the boiler pressure can not be raised, and that all parts of the engine are strong enough to carry the extra load?

21. Explain some type of ammoniac compressor, giving details of operation. How would you naturalize ammoniac fumes escaping from a leaky pipe in an enclosed room, and after this is done how would you locate the leak?

22. What is the safety head of an ammoniac compressor? What purpose does it serve, and how is it constructed? What precautions are necessary in taking compressor cylinder apart in order to prevent injury from inhaling ammoniac gas, if this gas should be inhaled to such an extent that a person becomes unconscious, what action would you take to save him?

23. What is the position of the eccentric related to that of the crank for engine running, either over or under (a) with direct motion; (b) with indirect motion; (c) with indirect valve and direct motion; (e) with expansion valve (righting cut off) direct motion, with indirect motion for some?

E. V. M., Lardo, B.C.

Answers to Questions In Last Issue

13. In the case of a safety valve blowing off at 80 lbs. when it has been operating at 100 lbs., the first thing to do would be to test the steam gauge and see if it was indicating correctly. If the gauge was found to be correct, and your safety valve was of the spring-loaded type, attention would be called to the spring. If the change had occurred suddenly, it would indicate a sudden failure of the spring, or if of gradual occurrence it might be due to a softening of the temper. If you had any reason to doubt the spring, it would be unwise to try and interfere with the compression while under pressure, as a sudden collapse of the spring, accompanied with a violent and large opening of the valve, would, perhaps, cause an explosion. It might be due to the easing gear becoming held up in some way. The safest thing to do is to shut the boiler down and examine the valve and gear. A safety valve not operating correctly ceases to be a safety valve. Sometimes a spring becomes fatigued when annealing, and re-hardening will remedy the trouble. However, do not run the boiler till you have found the cause.

In the case of the valve not lifting till the gauge showed 120 lbs., it would probably be a case of the valve spindle jamming, or the valve itself jamming in the seat. Note if the valve allows steam to go back to normal before closing, or if it blows down far below the working pressure. In either case, after the valve closes, try the easing gear, when steam is at or approaching the normal blowing off point. You can tell if it is sticking. If so, the only course again is to close down, and remedy whatever defect you find. Use your judgment, but don't take chances.

14. In setting the water column, arrange it so that when water is in the bottom nut, there will still be from four to six inches of water over the highest heating surface in the boiler.

If you had no means of testing the steam gauge with a standard gauge, you could still set your safety valve approximately. If a lever valve, you can arrange it by the principle of levers. If your valve is, say, 3 inches diameter, and the ball weighs 50 lbs., distance from fulcrum to valve spindle, 4 inches, required pressure, 100 lbs. per square inch. Then total load on valve will be $3 \times 3 \times .7854 \times 100 = 706$ lbs. The load on the valve multiplied by its leverage must equal the weight of the ball multiplied by its leverage. The steam pressure acting on the valve is the force. and the ball is the weight to be moved. We have F:W::2:L or $706 \times 4 = X \times 50 = 56.48$. The ball must be placed 4 ft. 8½ in. from fulcrum. This neglects weight of lever and valve, but is near enough.

If you have a spring-loaded valve, you can proceed in two ways. Suppose again your valve is 3 in. diameter, and pressure 100 lbs., your total load will be 706 lbs. Suppose your spring is 2 inches mean diameter, and ½ inch square steel, and there are 12 effective coils. By the formula

$$\frac{D^3 \times S \times n}{t^4 \times C} = f$$

where

D = mean dia. of spring.
S = load on valve.

n = number of coils.
t = thickness or dia. of spring steel.
C = 1,400,000 for round spring.
2,000,000 for square spring.
f = compression.

$$\frac{2^3 \times 706 \times 12}{\frac{1}{2}^4 \times 2{,}000{,}000} = .545$$

Therefore a compression of ½ in. on the spring will give the desired lifting point.

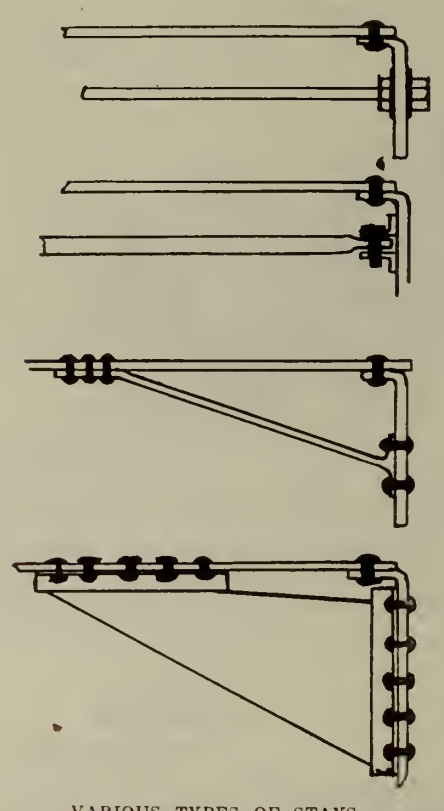
15. An expansion joint, as its name implies, is to take up the expansion in a length of steam pipe. On the end of one length a stuffing box is formed, and the end of the adjoining length fits into this loosely, a gland being fitted to ensure steam tightness. It is most important that guard bolts be fitted to prevent the pipe drawing out, as it is quite free to do so. A ring is fitted on each length of pipe, and suitable bolts are fitted, connecting the rings, with double nuts on the movable end of the pipe. Sufficient play is left between the double nuts to allow the pipe free movement, while preventing it by any chance drawing out of the gland.

16. A spring-loaded safety valve of the pop type is usually made with the spring enclosed within the body of the valve. The pop valve is made with a large lip on the valve, so that immediately it moves from the face an extra large area is exposed to the action of the steam, causing it to lift quickly. The same arrangement tends to keep the valve open till the pressure has dropped a little below normal. The ordinary valve is fitted with a lip, but not so large as the pop type, the effect in the ordinary valve being merely to overcome the extra compression of the spring, when the valve lifts.

The action of the safety valve is simple. The valve is connected to the steam space of the boiler, and the load on the valve is proportional to area X steam pressure. The size of the valve is governed by the grate area, being for low pressure ½ square inch valve area to 1 foot sq. of grate area, and for high pressures .3 sq. inch to one square foot. The load on the valve, due to the steam, is exactly balanced by the compression of a steel spring, thus holding the valve shut. When steam rises above the predetermined pressure, the load on the valve is greater than the resistance of the spring, and the valve rises, compressing the spring still more. It is to take care of this extra compression that the lip is formed on the ordinary spring-loaded valve, and the larger lip on the pop valve to ensure a rapid overcoming of the same. Provision is made in both types of valve to raise the spindle by hand, by fitting a lever which engages a cotter passed through the valve spindle end.

17. The breaking or ultimate strength of a boiler plate is from 60,000 to 65,000 lbs. per square inch of section, under a direct tensile stress. About half of that stress is the elastic limit of the material, that is, when stressed above 30,000 lbs., the strain becomes permanent. It is therefore necessary to make provision for the limiting of the working stresses below this point. Furthermore, such factors as workmanship, fluctuating loads, etc., have to be considered. Therefore, to make ample provision, when calculating the working pressure, a factor must be used that will leave an ample margin of safety. For a boiler of good material and workmanship, a factor of safety of 4 is taken, which means that the highest allowable stress will not be more than ¼ the ultimate strength of the material. This may be reduced to 1-5, or even less, by raising the factor of safety.

Frequent variations of pressure produce frequent variations of temperature, and different conditions of stress in the material. The result of this is a gradual



VARIOUS TYPES OF STAYS.

crystallization of the material, or fatigue, which reduces the elastic limit, and ultimate strength of the material.

The segments of boiler heads above the tubes are stayed by direct or diagonal stays, and by gusset stays. Direct stays are those which pass direct through the boiler from head to head, and are sometimes passed through the heads and secured by nuts and washers on each side of the plate. Sometimes a plate is fitted over the head, and called a doubling plate, which acts as a stiffener. In other cases the stays are formed with an eye, which fits between channel irons riveted to the head, a pin being passed through to hold them.

Diagonal stays are made either out of round or flat stock. When of round stock they are flattened out at each end to form a foot, which receives the rivets. The end attached to the head is sometimes turned to right and left, in which case the foot is welded to the stay. The head end may be formed into an eye and fastened between channels, as in the case of the direct stay.

There is also the Hewson diagonal stay formed by pressed steel, and made in such a way as to allow a certain amount of spring.

The gusset stay is a triangular piece of plate, fastened to shell and head with angle irons on each side.

The direct stay is the strongest and most simple. The only disadvantage it possesses, though in a small boiler it may be a serious one, is that it makes getting into the boiler difficult, and moving round after getting in also hard. The diagonal stay to be as strong as the direct stay must be of larger diameter, as owing to its inclination part of its pull is lost. That is, if H represents the height from shell to stay on head, and L length from head to point of connection of stay on shell; then, if area of direct stay equals 1, area of diagonal stay must equal

$$1 \times \frac{L}{H}$$

or strength of diagonal stay is equal to

$$1 \times \frac{H}{L}$$

Stays fastened to head by channel or angle irons have the disadvantage that the channels form a nest for the reception of scale, and unless care is exercised, the connecting pins corrode rapidly. The diagonal stay allows ample room to move about inside the boiler.

19. If the engine is equipped with a governor, the pulley can be altered to allow the engine to speed up. If a shaft governor is fitted increasing the tension on the spring will have the same effect.

If your engine has a pulley on crank shaft 10 in. diam. and on governor shaft 8 inches, engine revolutions being 100, the governor will run at

$$\frac{100 \times 10}{8} = 125 \text{ revolutions}$$

It is required to increase the engine to 110 revolutions, keeping cut-off the same. Therefore you must arrange so that governor will run the same speed with the engine at 110 revs., as at 100, in order to keep the balls in the same plane.

110 : 125 : : x : 10 = 8.8.

The pulley on governor shaft must be replaced by one 8.8, or, say, 9 inches, which will give

125 : x : : 10 : 9 = 112.5 revolutions.

In the case of the shaft governor, increasing the tension of the spring, or in some types increasing the weight must be tried till the result is as required.

The illustration herewith shows a section of a Linde compressor, double acting. The piston is made of the circular design shown in order to obtain

the minimum of clearance. There is a suction and discharge valve at each end of the cylinder. This type of compressor has no water jacket, the heat of compression being taken up by the evaporation of a small quantity of liquid ammonia injected at each stroke. The action is as follows:

Ammonia gas from the evaporation is drawn in by the piston at one end, while the charge previously drawn in is being compressed to a liquid at the opposite end When the compression has been completed, the pressure is sufficient to overcome the spring, and the liquid is forced over to the condenser. The same events occur on the return stroke.

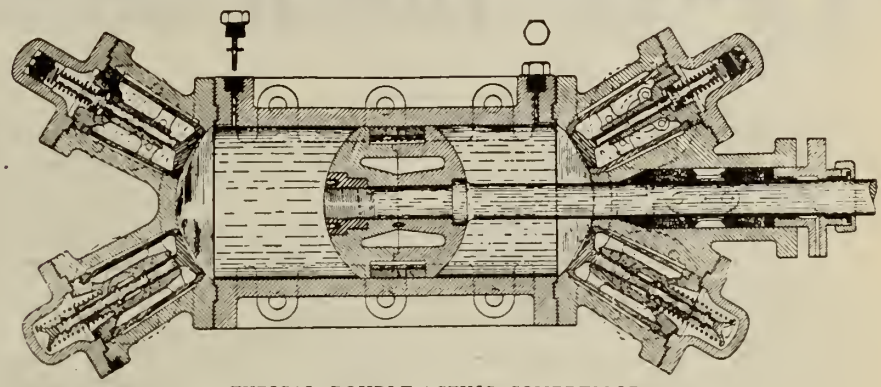
The way to neutralize the fumes of escaping ammonia is to saturate the fumes with water. Ammonia is readily absorbed by water, and a hose should be always handy.

If a man has become unconscious, get him in the open air, and give him warm milk up to a pint. If he is not unconscious, sucking a lemon, or drinking a solution of good cider vinegar will be of great value.

22. The safety head of a compressor is a false head, fitted with heavy springs to hold it in place, as shown in the illustration. The construction is such that in the event of an abnormal pressure, the head will lift exactly as a safety valve would do.

In taking a compressor cylinder apart be sure to drain all the gas away before opening up. This can be done by the by-pass arrangement fitted on many machines. Keep a hose handy to drown any fumes that may escape.

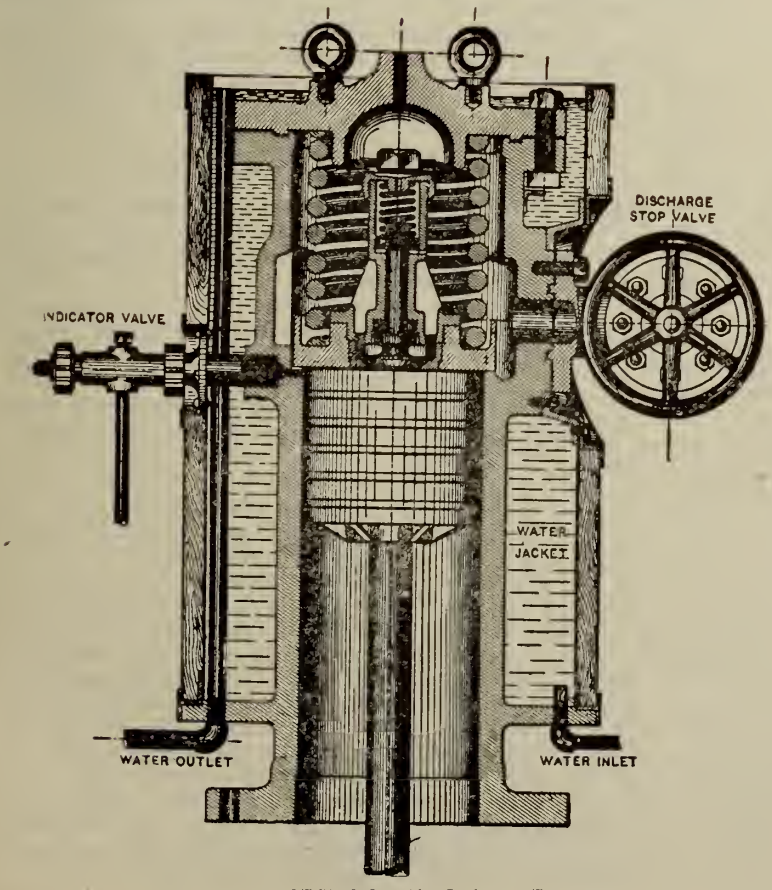
23. The position of the eccentric to the crank for a direct acting motion is that the centre line of eccentric is in advance of the centre line of crank by 90 degrees, plus the amount of cap and lead of the valve.



TYPICAL DOUBLE-ACTING COMPRESSOR.

With indirect valve and direct motion the eccentric will be behind the crank, instead of leading it, or with indirect motion and direct valve it will be behind the crank.

An expansion valve is usually operated by its own eccentric, and the position of this will be governed by the position of the main eccentric, and is usually about 180° from the crank.



SECTION SHOWING SAFETY HEAD.

THE USE OF BALL BEARINGS FOR ELECTRICAL MACHINERY

(Continued from page 224)

circulation of the lubricant in the ball paths: Oil rings, chains, or similar rotating oiling devices are done away with entirely and positive, thorough and uniform lubrication is assured.

It will be readily appreciated from the use of ball bearings on motors that:

1. They eliminate the frequent troublesome inspection of plain bearings—the user need not concern himself as heretofore about the possibility of oil rings sticking.

2. Motors equipped with ball bearings are free from the nuisance and dirty conditions caused by creeping oil and dust around the bearing heads. Frozen bearings due to oil or lint or draining of the oil reservoirs are practically eliminated. Security against such conditions in many instances is worth the cost of the motor and is particularly valuable in textile mills, flour mills, woodworking plants, or other paces where dripping oil adds to the fire hazard or is ruinous to stock in process.

Briefly summarizing the economies offered by ball bearings:

(a) Smaller air gaps permissible, because ball bearings will not wear down as plain bearings do. This gives an improved power-factor for induction motors.

(b) Danger of armature touching the pole pieces is eliminated.

(c) Leakage of oil is prevented. Thus oil cannot drip on to the commutator or oily dirt collect, causing flashovers.

(d) Over-all length decreased from 10 to 20 per cent, resulting in a more compact motor.

(e) Longer period between motor inspection and lubrication required—once in six months against once in two weeks with plain bearings.

(f) Fewer repairs and decreased maintenance cost.

(g) Improved motor commutation.

(h) Improved efficiency, because of reduction in bearing losses

A New Fuel For the Power Plant

IMPROVEMENTS are constantly being effected in power plant design and operation. The turbine room having reached a high state of efficiency it is only natural that engineers should be devoting their attention more and more to the boiler room and to combustion problems.

New fuels are being developed, and one of them, powdered coal, has reached the commercial stage. A more recent development, colloidal fuel, makes use of powdered coal and fuel oil in a combined fuel having a very high heat value.

Colloidal fuel is an American invention, primarily due to the war and developed for the conservation of the oil wells. It is merely a mixture of coal dust and oil, the coal dust being held in suspension in the oil by the use of some agent. Graphite and many other substances if reduced to a fine enough state of division may be suspended in a liquid indefinitely; such solutions are known as colloids. The coal dust used with fuel oil is not necessarily so fine as to remain suspended in fuel oil by itself and the inventor, Lindon W. Bates, has been able to effect the permanent suspension of relatively large particles in oil.

This new fuel has the advantage over plain coal dust, in that it can be fired through oil jets with quite a moderate air pressure, whereas powdered coal requires burners of a special kind. Colloidal fuel also overcomes the explosive characteristics of powdered coal.

In practice it is possible to use two parts of coal to one of oil and to obtain a higher heat value than by the use of oil alone.

Pessimists Get Out And Stay Out

HE was sitting in his comfortable office, and everything was going fairly well with the business. But that did not make much difference.

Things in general, according to him, were bad. Our exchange rate abroad was putting a millstone around the national neck; strikes and threatened strikes were putting the finishing touches on the ruin; conditions in Europe were so uncertain that nothing could help them.

In fact, he was out to spray with pessimism every person with whom he came in contact.

There should be some recognized and legal method for dealing with the likes of this. He ought to be "canned," to use the rather pungent talk of the street.

He is living in a great country, better than which there is none. He is right in the midst of one of the greatest periods for usefulness and common-sense the world has ever seen.

And yet this chap, just at the period when the world, and Canada in particular, needs his shoulder at the wheel, is sitting at the side of the road, hoping that the cart will start and slip down hill to jibe with his silly little notions.

It would be too much to expect that a world, which had been churned and shaken from centre to circumference for four years, would, at a day's or a week's notice, slide back and jog along just as though nothing had happened.

This country needs the sane optimism of clean-thinking, courageous men. It does not need the whines of the pessimist nor the groans of the blue-ruin brigade.

A Risky Occupation

THE Toronto *Globe* man has been figuring out the capacity of electric furnaces. Simple thing, too—just as simple as measuring snow with a stick, or stepping off a frontage with your feet.

The *Globe* goes on to say that Toronto has "the largest single electric steel plant in the world as far as known." So far so good. Then the *Globe* goes on to tell its readers just how great this great furnace is:—

"The ten six-ton Heroult furnaces at the British Forgings plant are capable of turning out sixty tons of high-grade steel per day."

Quite so, but why stop at sixty? The *Globe's* man has proceeded on the good old plan that two and two make four. Therefore, ten six-ton furnaces equal ten times six, which makes sixty! Splendid!

But the *Globe* might be surprised to know that this plant has turned out as high as 350 tons per 24 hours, even with its "sixty tons per day" capacity. As a matter of fact, these furnaces can take a heat every five hours, and if worked at anything near real capacity, can make five heats per day. Taking only sixty tons per day from such an outfit as the British Forgings have would be about the same as having a plant and staff equal to that of the *Globe* for the production of a weekly paper.

The *Globe* is quite right in stating that ten times six makes sixty, but it should also recognize that computing the capacity of electric furnaces is slightly different from painting the political situation at Ottawa.

Association and Personal

CANADIAN ELECTRICAL ASSOCIATION WILL HOLD ANNUAL CONVENTION

The Canadian Electrical Association will hold its annual convention at Alexandria Bay, N.Y., on June 27 and 28. Members of the association will leave by boat from Toronto and Montreal on Wednesday, June 25. The cessation of war activities and the return to normal conditions promise a most successful convention, with a number of very interesting papers.

TORONTO LODGE ELECTS OFFICERS

Toronto No. 1 Lodge of the Canadian Association of Stationary Engineers, held a well attended meeting at their rooms in the Temple Building, on Wednesday, May 28th last, for the purpose of electing officers for the coming year, and also electing delegates to the annual convention to be held in Brantford, on June 24, 25, 26th.

The following officers were elected for the ensuing year: President, S. Balmfirth; vice-president, Mr. Adam Taylor; treasurer, John Brown; financial secretary, Ross Leach; recording secretary, Thomas Clews; conductor, J. MacLaren; doorkeeper, Mr. Beach.

The following members were selected to represent the lodge at the convention: Messrs Brown, Balmfirth and Beach.

Business being concluded, the officers and members adjourned to Young's banqueting hall, Yonge Street, where a tasty cold collation had been prepared. The supper being disposed of, the president called the members to order, and the toast of "The King" was honored in foaming ginger ale. The toast of the city of Toronto, was proposed, and replied to by Mr. MacRae, of the Board of Education. In course of his remarks, Mr. MacRae alluded to the trouble in Winnipeg, and in moderate and well considered words showed how the sane and conservative members of the trades unions had been misled by irresponsible agitators. This was followed by the National Anthem, after which the gathering dispersed, well pleased with their evening's entertainment.

Mr. Balmfirth gives notice of a picnic to be held in the near future at which he hopes to see a large attendance.

Henry Engineering Co.—The Henry Engineering Co. announce the formation of a company of three well-known gentlemen, experts in their various lines. Their offices are at 71 Bay Street, Toronto, where they are prepared to act as consulting engineers on general engineering lines. They will also specialize in the purchase and sale of power equipment, steam, electrical and hydraulic, both new and used. The company is composed of Thomas Henry, James A. Rumgay, and Edwin B. McBryde. Mr. Henry was for many years chief engineer of the Interurban Co., and the Erindale Power Co. Later he was associated with the sales department of the Toronto Electric Light Co. Mr. Rumgay was for some years with the Canadian Allis-Chalmers Co. as draftsman and estimating engineer. More recently Mr. Rumgay has been designing engineer and manager of the boiler department of the Polson Iron Works, Toronto. Mr. McBryde has been, since coming to this country, assistant distributing engineer of Toronto Electric Light, and later assistant sales manager. For the past two years he has been manager of the Fisher Electric Co., Toronto.

GETTING OIL IN ENGLAND

By L. P.

The Government has decided to explore Great Britain for oil. There is no reason why our battleships should not be steaming on oil fuel got from beneath our own soil, nor is there any reason why some of our motor cars should not be driven by petrol from under the roads they run upon.

In the past we have been too careless of the wealth that lies under our feet, petrol, lamp oil, fuel oil from overseas were sold here so cheaply that no one was prepared to risk money in drilling for oil in England. But the war has changed the entire position, and petroleum has become so precious that if it exists under England, it must be searched for and got.

That it does so exist has been proved on many occasions during the last century or two. At Clowne, near Chesterfield, there was a flow of 700 to 1,000 gallons daily. Dr. James Young, the founder of the Scottish shale industry, manufactured products 70 years ago from a flow of oil at Alfreton, Derbyshire. A flow at Coalport, mentioned in 1836 by Dr. Prestwich, is stated to have formerly yielded 1,000 gallons a week.

But the most important discovery of recent years was made at Kelham, near Newark in August, 1911. A bore hole was put down there and obtained true petroleum at a depth of about 2,440 feet. The oil sand or rock that gave the oil, was about 13 feet thick, and the bore holes passed right through it. From this bore hole, five to eight gallons of oil flowed to the surface for many months, and was described by our principal authority, Sir Boverton Redwood, as a true petroleum.

Any qualified person who has examined a sample of the oil will agree with him. Provided enough of this oil could be obtained there is no reason why it should not be piped straight away to say, Hull, where a warship could take it on board as oil fuel, just in the state it came from the well.

But there is one remarkable thing about the Kelham oil. Nearly all crude petroleum in its virgin state contains petrol. The Kelham oil contains none. It is incomplete. There is reason to believe it did once contain petrol, if so where has that petrol gone?

The answer is the petrol has become separated from the heavier part of the oil. Where shall we find the complete natural oil with its petrol intact, as contrasted with the Kelham oil? Obviously not above the Kelham oil or the bore holes would have passed through it. Therefort it is said we ought to find it below the Kelham oil—possibly a thousand feet lower. This is a surmise and cannot be said to be a certainty.

Some of us have for years past been urging the Government to drill for oil. We have not predicted with absolute certainty that they will get oil here or get it there. What we have said is that it is worth while making the experiment and finding out whether in these critical times we can depend upon a supply of petrol or lubricating oils, and of liquid fuel, without bringing these from overseas.

The Government has wisely determined to search for oil in England. They have a good chance of being successful.

The Automatic Gas Regulator Company, capital $50,000, head office Vancouver, plans to manufacture and deal in gas regulators.

Hydro Buys Thorold Plant. — Mr. James Battle of Thorold has disposed of his electric power and transformer plant to the Hydro-Electric Power Commission. The price was $100,000 in four per cent. bonds. It is likely that the town will take over the plant. Mr. Battle had a 26-year contract with the Ontario Power Company.

Progress in New Equipment

NEW VULCAN SOOT CLEANER SWIVEL HEAD

FIG. 1 shows the new swivel head for the Vulcan soot cleaner, just put on the market by the Vulcan Soot Cleaner Co., Du Bois, Pa.

To be successful, a swivel head must provide for four things: (1) It must permit easy turning of the soot cleaner element by simply pulling the chain shown in either direction; (2) It must take care of expansion and contraction of the connecting pipe line; (3) It must not leak steam; (4) It must not permit air infiltration.

Steam from the boiler passes into the swivel head from the bottom through the vertical pipe shown, and thence into the horizontal element which extends from the swivel head through the brick wall and into the setting. Fig. 2 shows an interior view of the cleaner element as applied to a Stirling boiler.

After the steam is turned on, the operator rotates the element slowly from one extreme to the other. Steam turbine nozzles inserted in the element and correctly spaced discharge the steam between the tubes in high velocity jets, and in the course of rotation the tubes are thoroughly freed from soot. The limitations of rotation are easily regulated by stops attached to the link chain. These stops are stopped by the horizontal cast fingers shown. A pointer from one arm of the sprocket plainly indicates to the operator the direction in which the steam jets are discharging. This pointer is plainly shown in Fig. 1.

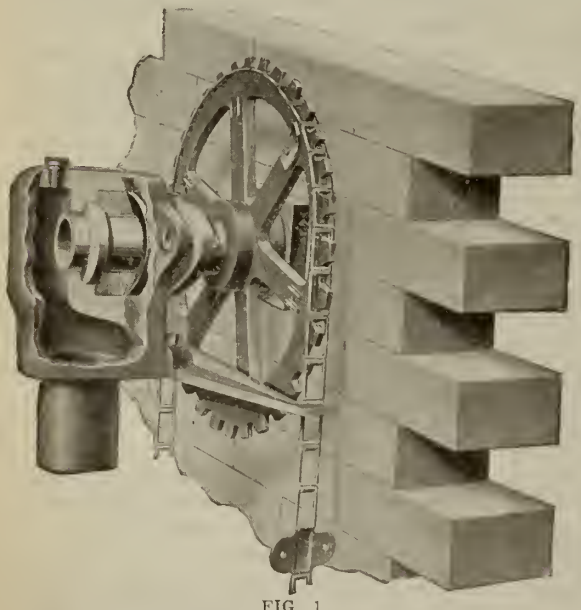

FIG. 1.

The method of packing the stuffing box in the swivel head is clearly illustrated. The visible end of the element, Fig. 1, is made of bronze composition on which is turned a collar that fits against metal on one side and packing on the other. It is designed in such a way that when steam is turned on friction is relieved and turning the element by hand becomes easy. In their broad experience at soot cleaning the manufacturers have learned that the operator is less liable to shirk his duty where manual labor is eliminated or reduced to the minimum.

To take care of expansion and contraction, a gas tight, sliding joint is provided between the sprocket wheel and the metal housing that is mortared into the brickwork. Hence the ample clearance shown in Fig. 2. As the vertical riser expands or contracts, the swivel head moves up or down and the attached end of the element must, of course, follow. This is nicely cared for in the new Vulcan sliding, rotation swivel head, which is so designed that air inleakage becomes impossible because of an air-tight plate used in the sliding joint.

As is well known, in ordinary settings, where the hand lance is used for cleaning, air inleakage is enormous and much fuel is lost, due to that cause alone. The effective sealing up of all cracks with the installation of a mechanical soot cleaner is in itself an important coal-saving item.

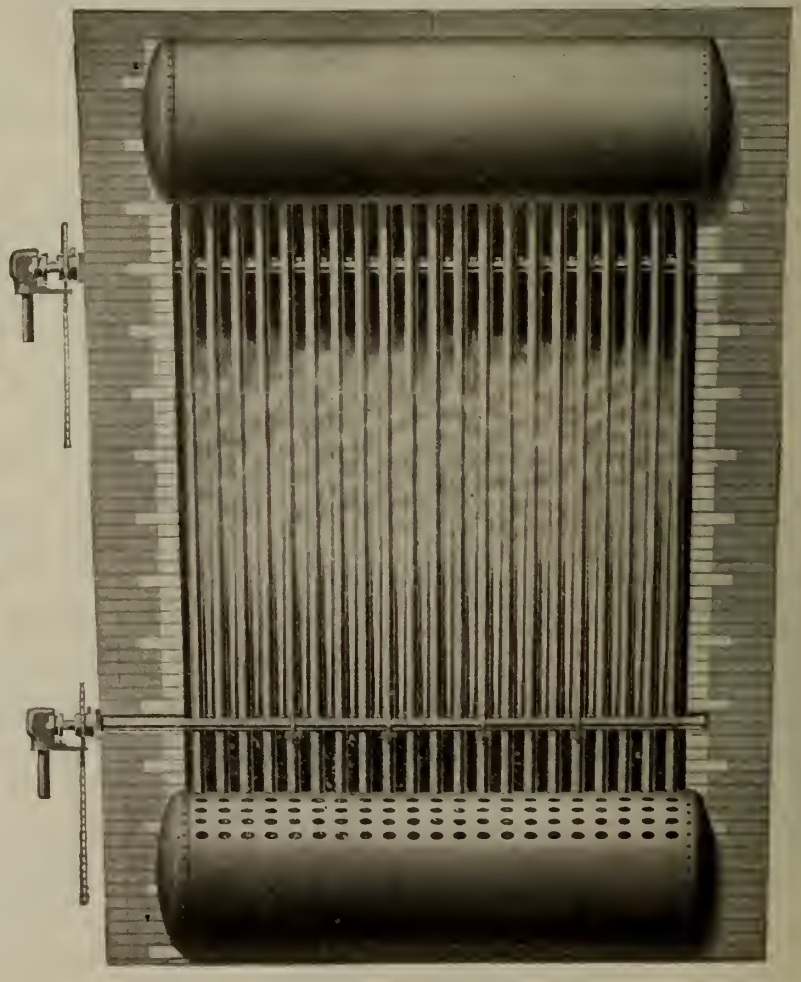

FIG. 2.

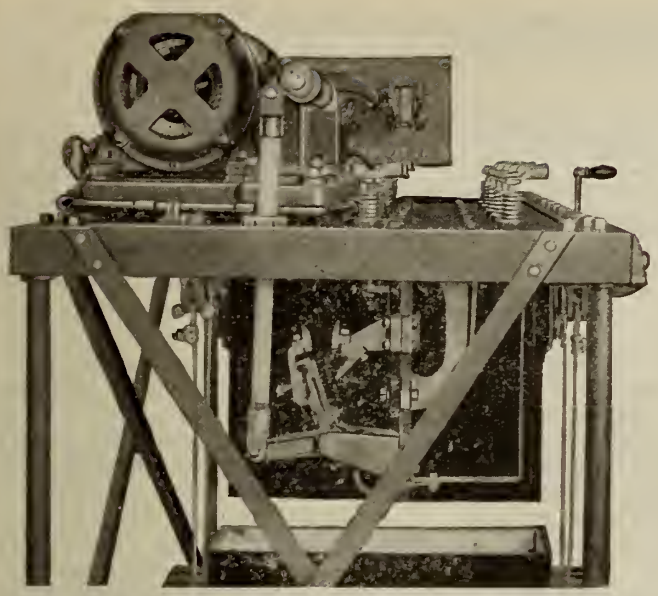
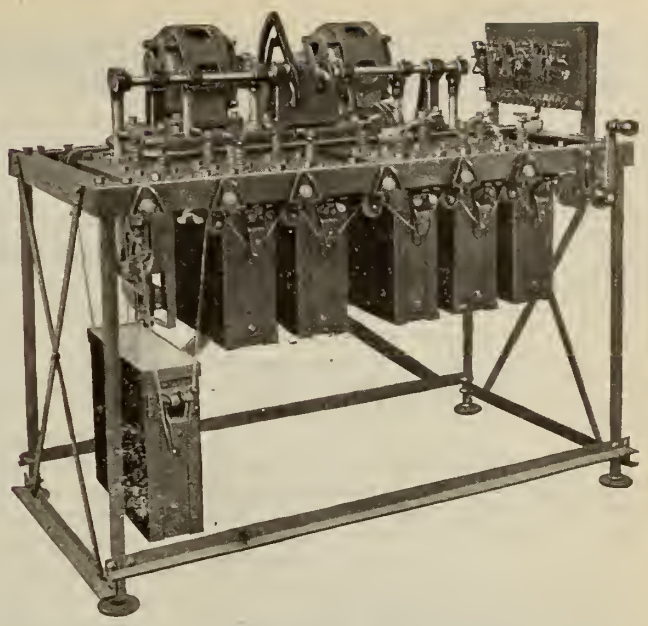


THIS END VIEW SHOWS THE CONSTRUCTION OF THE CONTACT-MAKING MEMBERS; THE ARC BEING BROKEN HORIZONTALLY RATHER THAN VERTICALLY.



NEW PRIMARY OIL REVERSING SWITCH WHICH IS VERY QUIET IN OPERATION, BEING OPERATED BY TWO HIGH TORQUE MOTORS.

NEW OIL REVERSING SWITCH FOR LARGE MOTORS

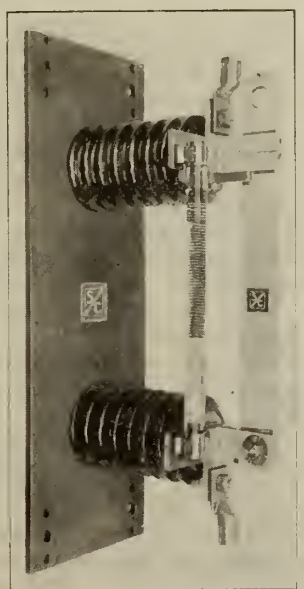
High voltage slip ring motors built for steel mills, mine hoists and similar duty, require some form of switch to connect the primary winding to the lines, especially so when the motor is used for reversing service. The accompanying illustrations show a new primary oil reverse switch that has several new and interesting features. It consists principally of two 3-pole switch units each operated by a high torque motor.

Among the unique features of this switch are the unit tank construction and the means of lowering the tanks for inspection, repairs and renewal of oil. Unit tank construction is used because it increases accessibility and saves time and labor in locating trouble and making repairs. A double windlass with cables and pulleys permits easy lowering of one or more tanks. In the end view one of the tanks is lowered and shows the simple construction of the stationary and moving members. It will be noted that the arc is broken horizontally, rather than vertically. This construction allows the arc to rise to the point of rupture without burning parts not designed for such duty; and since the rupture takes place near the top of the oil, it is well away from all sediment; hence frequent inspections and renewals are unnecessary. The support for the stationary and moving members is bolted to a channel iron, which in turn is bolted to the main frame, consequently in case of serious damage to any single pole unit the complete unit may be removed without disturbing any of the others. The tanks are lined with a heavy asbestos material to prevent groundings of any live parts in case the tank is pushed out of place, and also as an additional safeguard in case of sludging of the oil.

The contractor panel shown at the extreme right is controlled from a master switch or push buttons and handles the motor currents. Very little current is required, as the motors used have high resistance motors. This particular reversing switch was made by the Cutler-Hammer Mfg. Co. of Milwaukee for a 1,200 h.p. 220 volt mine hoist motor. It may be used for two motors on non-reversing service, or where only one non-reversing motor is required the switch is made with only one 3-pole unit and one motor.

S. & C. SAFETY DISCONNECTING SWITCHES

The hazard attending the opening of disconnecting switches that are alive but which are not supposed to be carrying current, is only too well known to operating engineers. The disastrous results have taken a heavy toll in lives, besides the enormous damage done to apparatus and to the morale of operators wherever these accidents have occurred. These accidents are by no means necessarily the result of carelessness on the part of operators, as there have been many cases where oil switches have failed to operate properly, and, since the contacts are enclosed in the oil pots, there was no way of knowing that the contacts had not separated and that the disconnects were still carrying current. After the disconnecting blade has been opened and the resulting arc has flared into the surrounding structural iron, it is too late to rectify the error.



SAFETY DISCONNECTING SWITCH.

In addition to the desirability of making the operation of disconnecting switches safer, there also exists a large field for an inexpensive method of interrupting load currents at moderate and high voltages without the use of expensive oil circuit breakers. This is especially true in those cases where the opening of the circuit is necessary only at rare intervals.

There have been many attempts to provide devices to insure the safety of the operator and to make possible the interruption of high voltage currents, but the adaptation of the S. & C. fuse to this purpose, is, without any doubt, the simplest and most reliable of all such devices. The arrangement of the S. & C. fuse for this purpose is shown in the accompanying illustration. It will be noted that it consists essentially of a disconnect shunted by a low amperage S. & C. fuse, and provided with a lock, so that the disconnect cannot be opened unless the fuse is in place. If the disconnect is opened when it is carrying current, the current is shunted through the fuse where it is interrupted when the fuse blows due to the current being above the rated current of the fuse.

A very noteworthy fact is that in interrupting currents at 9,000 volts, it was not necessary to open the disconnect with any unusual rapidity. The ordinary rate of opening the blade was

quite sufficient to shunt the current through the fuses and prevent the arc from being reestablished at the contact. In regular service it is, however, desirable to open the disconnect with as quick a movement as possible.

In order to be positive as to the possibilities of the safety disconnecting switch, a great variety of loads were interrupted, covering everything from an exciting current of compensators and transformers, to the breaking of single and three phase load currents. The results were the same in each case, in that there was scarcely any visible evidence that any current had been interrupted.

The adaptability and utility of such an arrangement is at once apparent. It represents a very small additional cost to the equipment, and at the same time, provides positive insurance against the inevitable damage, and perhaps loss of life, whenever a blade disconnect is opened while carrying current. Such insurance is especially desirable in the case of oil switch disconnects, regulator transfer switches, etc., where the space around the blade is very limited, and where, therefore, an arc would result disastrously.

It should be remembered that the fuse only blows in case the disconnect is carrying current when it is opened, and there is no expense involved unless current is interrupted. On the other hand the cost of refilling an S.&C. fuse is quite infinitesimal when compared with the cost of repairs after an accident of this nature, for it must be remembered that when once an arc is started between a live contact and grounded framework, such as surrounds all installations of this kind, only the opening of the oil switch controlling the source of supply can stop the flow of current. The expense of occasionally filling an S. & C. fuse is, of course, negligible when compared to the advantage of the S. & C. safety disconnect idea. carrying load. and therefore avoid the installation of costly oil circuit breakers.

If safety disconnecting switches are used it is not necessary to provide ordinary positive locks to keep the switch from opening, due to magnetic forces when short circuits occur. The safety lock performs its regular function and this function also. Ordinarily the safety fuse would not be in place. and. therefore, the switch would be locked. It might be well to emphasize that although there might be many safety disconnecting switches in a station, only a comparatively small number of fuses need be kept on hand, as they are only inserted when it is desired to open the disconnect.

Another invaluable feature of this adaptation of the S. & C. fuse is the effect upon the morale of the operating force when they know this danger in opening disconnects has been removed. Particularly is this so on systems where such accidents have happened. Experience has shown that length of service does not afford immunity, for quite often the trouble lies in other people and in apparatus beyond the control of the operator.

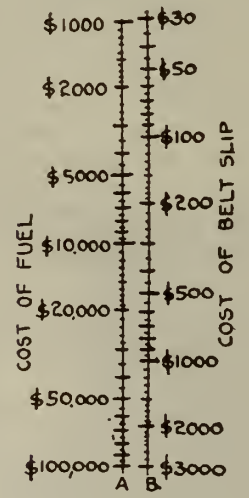
These safety disconnecting switches and fuses are manufactured by Schweitzer and Conrad, Ravenswood Ave., Chicago.

THE COST OF BELT SLIP

The Cling-Surface Co., Buffalo, N.Y., in its more than 20 years of existence, has done much toward conserving fuel and saving belts by eliminating belt slip. It has made belt slip and its attendant costs and troubles a special study. Readers will therefore be interested in the small and handy accompanying chart and the "Cling-Surface Formula" for more accurately figuring costs.

Referring first to the chart, column B shows roughly how much money Cling-Surface will save.

For example, if you spend $10,000 per year for fuel (see column A) and if all the power developed is sooner or later transmitted through belting. Column B



COST OF BELT SLIP IN TERMS OF FUEL CONSUMPTION

(opposite the $10,000) shows that $300 can be saved by stopping slip.

In the above scale 5 per cent. total slip, including creep, is assumed, which is a very low assumption.

If all the power is transmitted through a main belt and the main belt slips 5 per cent., the annual preventable loss in that one belt is $300.

Power is often transmitted from the main shaft to the second shaft, from the second shaft to the third shaft, and so on. This loss multiplies until the total often amounts to 10, 15, or 20 per cent. of the yearly cost of the fuel.

In the face of these facts it is evident that the cost of Cling-Surface is practically "zero" when compared with the money it saves through elimination of slip.

To assist the reader still further in correctly and simultaneously computing slip and costs this formula has been developed:

$$C\left(0.98 \frac{dn}{Dn}\right) = \$ \text{ wasted per year}$$

where—C = cost of power per year for the given drive, dollars:
d = diameter of driven pulley plus belt thickness, inches
n = r. p. m. of driven pulley
D = diameter of driving pulley plus belt thickness, inches
N = r. p. m. of driving pulley

If the reader doesn't like formulas, it can be done by following these simple rules.

(1) add diameter of pulley to belt thickness, inches, and multiply by r.p.m. of driven pulley.

(2) add diameter of driving pulley to belt thickness, inches, and multiply by r. p. m. of driving pulley.

(3) divide (1) by (2)

(4) substract (3) from 0.98

(5) multiply (4) by the cost of power in dollars per year for the drive.

The result is the dollars wasted per year because of unnecessary belt slip. The function of belt treatment is to save these dollars, an accomplishment that is possible by proper study, care and application.

A FILE IS A FINE TOOL

The Ingersoll File Company, Ltd., is sending out the following notice with its shipments of files:

The point of each tooth on it is as beautifully sharp as the edge of a good chisel. If carelessly handled some of these teeth are broken, with the result that the next time the file is used it seems dull and makes furrows or ridges in the work.

DON'T throw files carelessly into the drawer with cold chisels, hammers, etc.

DON'T leave files lying around on the bench or lathe where they are liable to be swept on to the floor and broken. Hardened steel is necessarily brittle, and we take a pride in making our product as highly tempered as we know how.

DON'T keep files in a damp place. Rust will ruin the best tooth ever cut on a file.

DON'T use a file for any other job than that for which it was made. Because it is "only a file" is no reason why it should be made the "Handy Man" of the shop.

May we suggest that you provide a rack for your files as you do for your drills, etc, so that they may be properly stored when not in use.

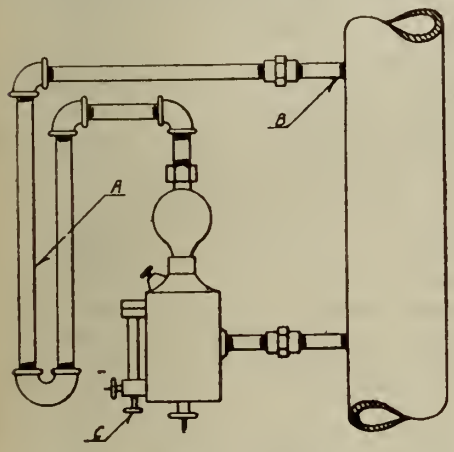
If these suggestions are acted on we think you will find the life of your files materially lengthened, and that they will keep their cutting edge, in which case you will be better satisfied as users and we as producers.

Always remember, a file is a fine tool.

The Operators' Point of View

LUBRICATION ATTACHMENT

The following idea may or may not be a new one. An engineer informed me that he connected his lubricators as shown and he found the regulation much easier than when he had the connection B several feet above the lubricator, his idea being that the pressure head in a long pipe requires a nearly closed feed valve, that when filling the lubricator the condensing pipe might be emptied and the feed valve would be opened enough to give a desired feed; gradually the long pipe would fill up, the pressure



LUBRICATOR CONNECTION.

would thus increase, and the oil would feed faster and the feed valve at C would have to be closed until the desired feed was secured; if it was neglected the lubricator would soon empty. With the trapped connections there is very little hydrostatic head, and the trap will hold the water when the lubricator is being emptied before refilling with oil, and the regulation is much easier, usually the first setting being right.

JOHN JAMES.

THE OLD HAND-FIREMAN TALKS

Oh, mister, what of the night,
Fresh air I seldom see,
I tell you I'm nearly tired to death,
Don't talk of the busy bee.
Just look in that hole, so black and grim,
So full of dust and grit,
I spend my life with my mates down here
With nary a chance to sit.
It's shovel and drag and poke the coke,
And slice and shovel and draw,
Is it any wonder I am a grouch
And say I am treated raw?
Sure I am a fireman, sir,
A hand-firing man at that;
I don't give a cuss for any machine,
I'll beat the best ones flat.
You say I could sit and read and eat,
And take things kind o' slow,
If I had your stoker machine
Attached right where my fires do glow,
There's nary machine on earth can stay
In this old game with me,
I hope the boss won't fall for it,
I'll put him wise, begee.
I love this darned old cheery dump,
I've been here half my life;
I know every danged old brick in the wall
As well as I do the wife.
The units of heat in the coal I fire
Come out and work for me,
Although a few run up the stack
They're as white as you or me.
The fires are level as mill-planed boards,
With nary a hole to see;
The grates I use have been here for years,
In fact since ninety three.
You ask me why I sometimes grouch,
And why do I raise a howl,
Well, mister, I'm getting old,
And an old man likes a growl.
I guess your mechanical stoker is fine,
But it can't compete with me,
For the human machine with a pride in its work
Beats the iron machine, you see.

THE OLD FIREMAN.

WHICH ARE BEST—PLUGS OR CAPS?

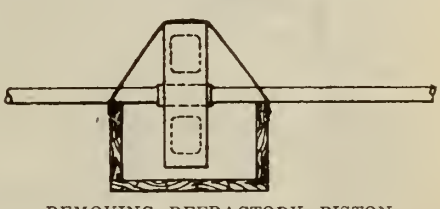
Around steam plants one often finds discharge pipe ends closed by putting on a coupling and inserting a plug. In high-pressure lines this is sometimes done where a leaky valve is on; the plug stops the drip. I prefer to use a pipe cap for the purpose because the hot water or steam does not fly out around one's fingers. One is only inconvenienced by the heat conducted through the metal of the cap and only one fitting is used instead of two. Every plant uses plugs, but one comparatively seldom finds caps on hand, and even some dealers fail to stock them, probably because they are

seldom asked for. The sketches indicate the difference of direction of flow of the hot water or steam in the two methods.

J. E. McCORMACK.

REMOVING A STUBBORN PISTON

A 16-inch piston on a 10-foot rod refused to yield to the influence of a 25-pound sledge. Not caring to apply fire to the piston and perhaps figure in the casualty list, we laid the rod across a box as per sketch and covered the piston



REMOVING REFRACTORY PISTON

and box with canvas. After heating the piston by means of a steam jet discharging into the box, and then cooling the rod with water, a little more persuasion from the sledge induced the piston to yield. It was safer than the fire method as the piston was cored and might have contained water.

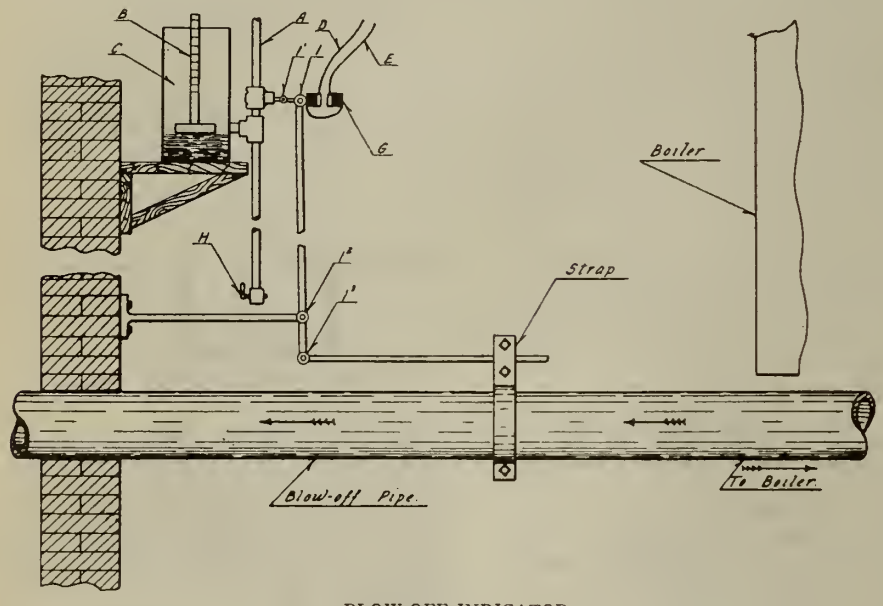
R. McLAREN.

STEAM BOILER BLOW-DOWN RECORDER

By Wm. Beecher

I have described several of these recorders in the past; the one herein shown is more simple and easier made than any of the others. It will do good work. Any man with ordinary ability can put it together. A strap is fastened around the blow-off pipe to hold a ⅜-inch iron rod with movable joints at 1, 1^2 and 1^3. A brace is attached from the wall to the rod as shown. If there is a night-watch clock in the building the wires D and E can be run to it; the two square pieces at G are attached together with a fine piece of spring wire, the piece at side, G, being fastened so that it will not move. The other piece is left loose, the spring allowing it to be moved to come in contact with the other one. The dark part is insulating material, the light part brass or copper, to which the wires are soldered. When the boiler is blown the pipe expands in the direction of the heavy arrows. This will force the two squares together at G and the time clock will record the hour and duration of the blow-down. If a pen record is used no change need be made; if a punching check is used the punching pin will have to be filed so that it will slit the paper disc should the blow-down be prolonged.

If no clock is used an ordinary outfit with the bell or buzzer in the office can be attached, and to show the duration of the blow-down a water tank as shown can be put up. The tank is a piece of 2-inch or larger iron pipe closed at the bottom and open at the top, a ⅛-inch water pipe is at A, a threadless spindle globe valve being at 1', a loose joint being there also. Inside the tank is a float with an indicating rod attached. When the blow-off pipe expands it opens the water valve and forces the electric connections together. By experiment the amount of rise of water in the tank per minute, or per inch of fall of water in the boiler can be noted, and the spaces marked on the rod B. This same rod should have as a guide a piece of sheet iron with a hole in it laid across the top of the pipe. If a piece of 2-inch pipe is used the float could be made the full size of the pipe, the markings being put on the float.



BLOW-OFF INDICATOR.

I feel sure that recorders of this style will be fairly accurate as the temperature in the blow-off pipe will drop very rapidly for the first 100 degrees or so, after the blow-off cock is closed. With a fairly long upright rod an expansion of 1-16th of an inch at the pipe will give a movement of ½ an inch or more at the valve. That is all, the sketch shows the idea very distinctly.

OBSERVATIONS OF A GREENHORN IN THE ENGINE ROOM

By WM. WEBB

ONE evening recently the boss called on me, and asked me if I would take charge of the engine and boiler next day, as the engineer was sick. I told him that nothing was easier. He had probably noticed that my bump of intelligence was abnormally large, and thought that I was capable of running his plant for a day or two. I am a woodworker by trade, but in my visits to the engine room I had taken particular notice of the duties of the engineer. All I ever saw him do was to throw a few shovelfuls of coal on the fire, cast a wise look on that clock thing up on the boiler, look at his engine, then sit down and read the POWER HOUSE. Anybody could do that. I hardly slept that night. I could fancy the fellows coming in, and saying, "Hello, Chief." Well, I got up, good and early, and went to work. My hat was a tight fit that morning. The night watchman had steam up, ready to start the engine. I told him to go home, and I would look after the rest. Our engine is a Wheelock, and I had noticed the engineer take hold of a handle, rock it back and forth a few times, and away she would go. As easy as falling off a log. Well, I turned on the steam, seized the handle, rocked it back and forth, but the engine refused to run the right way. It gave two or three revolutions backwards, and put half the belts in the shop off the pulleys Well, by great good luck she took a notion to run right, and away she went. And, by jimmy, she did go. I had never seen that engine go so fast. I was the boy to speed her up. But one of those know-it-all's came running in and shut off the steam. I said. "What did you do that for?" He said. "She was running too fast, and shaking everything to pieces." I suppose that is the reason that engines are always called "she." The engineer had taken a piece out of the belt that drives the governor, and had not put it on again. You could hardly blame me for that. Well, we put the belt on and turned on the steam. Not a move. One of those blamed pots would not work. Our engineer is not given to strong language, but I have heard him call those things, "dashed pots." Well, this same fellow moved some little lever under the governor, and the blamed dashed pots worked alright, and the engine started up once more. I thought my troubles were over. Well, I threw some coal on the fire, and I thought I would attend to the dynamo. The dynamo is driven by a belt connected with the engine. Our engineer claims that a dynamo should be driven by a little engine all by itself. And by this time I was beginning to have some little respect for the engineer and his job. Well, I started the dynamo, and pulled the switch from the city lights to our own lights. Result: Complete darkness. Back I switched to the city lights. In came Mr. Know-it-all. "What's the matter, Bill?" I told him the governor of the dynamo wasn't working, or else some blamed dashed pots were out of order. Well, he told me to turn a little wheel, then move the switch. I did so, and, by jimmy, the lights were on. I discovered that by turning that wheel that I could make the lights brighter, and so I turned till the clock thing was up to one hundred and forty, which was as high as the dashed thing would go. I tell you, our engineer never gave us such good lights as I got from that old dynamo. I then went to see to the fire, well pleased with the way I was progressing. I think I will take out engineer's papers. The fire was nearly out, so I threw in enough coal to last about an hour. I wanted to sit down and read for awhile. Pon my word, in came that Mr. Know-it-all again. Says he. "Where's your water" Says I, "In the tap, Smarty, and there's a cup, drink all you want." He says, "I mean where's the water in the boiler, I don't see any in the glass?" Well, 'pon my word. I had forgotten to start the pump. Well, we soon had the pump going, and I began to think that he did know a little about engineering. While we were attending to the water, the lights began to grow dim, till finally they went out. I made a rush and switched on the city lights. And that dynamo, instead of sending the light out to the shop, was keeping it all on the armature. There was enough light flying off the brushes to light three factories our size. Mr. Know-it-all says that the dynamo wanted a cleaning, and to get a piece of waste and clean it off. I remembered that the engineer put coal oil on the waste, so I got a piece, soaked it well, and applied it to the armature. Well, it blazed up in my hand, and burned my fingers. This gave me an excuse to go to the doctor, so I gave Mr. Know-it-all full instructions regarding the running of the plant, and beat it to the doctor. I got my hand bound up with about ten yards of bandage, and took dashed good care not to go back to work till the engineer was on the job again. I have decided not to apply for engineer's papers.

F. D. Still, vice-president and secretary of the Canadian Sirocco Company, has left on an extended trip for the far East, where he will investigate trade conditions in connection with export work. Mr. Still's itinerary includes Japan, China, Australia and most of the European countries and he expects to cover approximately 36,000 miles before

The Lubrication of Refrigerating Machinery

Special Attention Must be Paid to the Proper Lubrication of Compressors to Secure Highest Efficiency—The Proper Oils to Use Depend Upon the System Used

WHILE at first glance the lubrication of refrigeration machinery would appear to be little different from the lubrication of other apparatus of a similar type, a little thought will show that the refrigerating medium employed and the effects of the lubricant on the operation of the system will have to be taken into consideration.

In the absorption system where aqua ammonia is used as the refrigerant the only moving part is the pump, which does not present any difficulty in its lubrication unless where, in the case of a steam driven pump, the exhaust steam is required for ice making.

In ammonia compression systems the ammonia vapor is compressed from a pressure of 150 to 180 lbs., and from the compressor goes to the condenser, where the heat resulting from its compression is extracted and the gas liquefied. The anhydrous ammonia is now in a liquid state and still under pressure is expanded in the expansion coils. In its expansion it absorbs heat and returns to the compressor. An oil extractor is usually inserted in the line between the compressor and the condenser and any lubricating oil carried over thus entrapped.

In an article in "Southern Engineer" the Lubricating Engineers' Association of the Texas Co. make the following recommendations concerning the lubricating of ammonia compressors:

Lubrication of Compressor Cylinders

The characteristics of a suitable oil are such as any high grade air compressor oil would possess. The temperature during compression is comparatively low,probably not over 250 degrees, and as practically all of the oils that would ever be used have a flash point of over 300 degrees, this feature may be entirely disregarded in the selection of the lubricants.

The mechanical condition of the cylinder wall, piston, piston rings and valves determines the viscosity of the oil that should be used, as the oil must assist the piston rings in maintaining perfect compression. If the cylinder and moving parts are in first-class condition, a light bodied oil will give satisfactory results, but if the cylinders are worn out of round through usage or are scored because of improper lubrication or by the presence of foreign matter, a medium or heavy bodied oil should be used. An oil of medium body will greatly improve the seal of the piston rings and cylinder and will increase the efficiency of the compressor.

While an oil having the above-mentioned characteristics will satisfactorily lubricate the compressor cylinder, there are a number of other operating factors to be considered which frequently make necessary the selection of an oil of other physical characteristics. Regardless of how high the flash point may be, some vaporization will always take place under the high temperatures of compression, and this vapor will be carried out of the cylinder with the ammonia gas. As the compressor cylinder, the condenser, receiver, and expansion coils constitute a closed system, any oil vapor taken out of the compressor cylinder necessarily remains in the system, and, unless condensed and removed at some point, will gradually cover the internal surfaces of all parts of the system.

All oils, as they become cooler, thicken, until, at a certain temperature, they cease to flow and congeal into a thick, heavy bodied mass. In the event that the oil vapor reaches the condenser and expansion coils it is cooled and liquefied and unless it has a pour test lower than the temperature in the expansion coils it will congeal on the inner surface of the tubes. This congealed oil in addition to obstructing the passage of ammonia forms a very effective insulator, preventing the transfer of heat to the ammonia and seriously affecting the efficiency and capacity of the refrigeration system. To reduce as far as possible the loss due to the congealing of oil on these surfaces, the lubricant should have a pour test not above zero F., and lower if possible, so that any oil passing the traps and reaching the expansion coils will remain fluid enough to be carried along in the usual cycle of expansion and compression of gases.

Paraffine oils can be made suitable for ammonia compressor lubrication only after careful extraction of the paraffin by refining, a process which lowers the cold test.

To reduce the possibility of oil reaching the coils, all refrigerating machines and their accessories are equipped with oil extractors placed between the compressor and the condenser. These oil trapping devices should be carefully located and constantly watched to see that they are working properly, and are drained at regular intervals. Common practice in connection with determining the efficiency of such devices is to check up the amount of oil removed from them with the amount fed to the compressor cylinder. Any great difference is immediately investigated as it would indicate that the oil is not being entirely trapped. In any case the oil supplied to the compresspr cylinder should be reduced to a minimum. A surprisingly small amount of oil is required to lubricate the cylinder, and any excess amounts fed are likely to cause trouble.

The location of the oil extractor between the compressor and the condenser, and its efficiency, have a great influence on the viscosity of the oil which may be used in the cylinder. If the oil extractor is located close to the cylinder, a relatively high viscosity oil should be used, as the higher viscosity oils have less tendency to vaporize and be carried over with the ammonia gas. On the other hand, if the extractor is placed at some distance from the compressor, a lower viscosity oil may be used, as the oil vapor has a greater length of time in which to condense out of the ammonia gas before it enters the condenser. Consideration of the location of extractors is of vital importance in the selection of the compressor lubricating oil.

Medium bodied paraffine oils which might be suitable in viscosity for the lubrication of worn cylinders or piston rings have a high cold test which renders them unfit for refrigerating work.

Compressors are made in many types and forms and are lubricated in many ways. The cylinders of machines like the Remington, the Brecht and the Brunswick are lubricated by the splash system, the oil being carried in the crank case at a predetermined level indicated by a gauge glass and splashed on the parts to be lubricated by the rotating crank. The Brunswick and Remington machines are single acting with one end of the cylinder open so that the splashing of the oil on the inner surface of the cylinder lubricates it in a similar manner to the lubrication of automobile cylinders. The Brunswick machine has two piston rings below the suction inlet, which serve to wipe off excessive oil and prevent its being drawn into the cylinder.

There is a possibility with this method of lubrication that, in the event of the operator neglecting the machine and allowing the back pressure to drop below atmospheric pressure in the cylinder the low pressure in the cylinder may cause a considerable quantity of oil to be spashed up on the lower part of the cylinder to be drawn in. Such an occurrence, however, is almost always the fault of the operator, and with proper attention may be prevented. Oil losses may be reduced by blowing back into the crank case under pressure the oil carried over from the cylinder and deposited in the oil extractor.

Some compressor cylinders are lubricated by circulating oil through the piston rod stuffing box, which is especially arranged with an oil lantern. A

small amount of oil works into the cylinder through the packing and affords lubrication. The oil in the stuffing box lantern also protects the packing from the action of the hot ammonia gas which would have a very bad effect on the packing if it were not for the efficient protection afforded by the oil. Some compressors are equipped with mechanical force feed lubricators or lubricators connected between the intake line and the discharge line, the difference in pressure serving to force the oil through the regulating valve into the intake line.

As a point of interest to operating engineers, who may have had trouble with oil passing the oil extractors and congealing in the condenser, experience has shown that this accumulation may be removed by cutting off the water from part of the coils at a time and allowing them to become hot. This thins down the oil and it may be drained off at the oil trap. If the expansion coils have become coated, the oil may be removed by running the system backwards; that is, bp passing the hot ammonia gas back through the coils, warming them up, and melting down the congealed oil. Sometimes these coils are cleaned by pumping out all of the gas and blowing out the coils with steam and finally with air to remove the moisture. This is dangerous, as some water may remain in the system and have a bad effect on the ammonia.

Steam Cylinder Lubrication

Unless the exhaust steam is used in making ice. the lubrication of the steam cylinders of steam driven refrigeration machinery and steam pumps presents no unusually difficult lubricating problem. A high grade steam cylinder oil should be selected to meet the operating conditions, bearing in mind the principles involved in the lubrication of ordinary types of steam cylinders. However, if the exhaust steam is condensed and used in making ice, very careful arrangements must be made for the removal of practically all of the oil. For this purpose, oil separators are placed in the exhaust line, and upon their efficiency hinges, to a considerable extent, the selection of a proper oil to be used in the steam cylinders. When the live steam contains moisture, a mineral cylinder oil containing a percentage of fatty oil will give the best results, and is, in some instances, absolutely necessary to prevent cutting of the cylinder. On such installations a highly filtered oil should be used as sparingly as possible, and the oil separator should be blown out frequently. Where the steam is reasonably dry, a filtered straight mineral steam cylinder oil may be used if care is taken in the selection of the oil and the method of application. The oil should be introduced into the steam line far enough back from the throttle to insure complete atomization before it reaches the cylinder, as such atomization will permit of the use of minimum quantities of oil.

The discoloration of ice is the most frequent source of complaint from the engineers and operators and in practically all cases it is at once blamed on the oil. If the oil is not completely removed from exhaust steam used in making ice, a fan shaped discoloration appears in the block of ice. Rust formed by condensed water left in the cans is often the cause of ice discoloration, which can easily be distinguished from oil discoloration, as it appears all through the block and is without definite formation.

The carbon dioxide machine presents practically the same lubricating conditions as the ammonia machine except that the working pressures are from 900 to 1,000 pounds. The compressor cylinder temperatures are a little higher than those found in ammonia cylinders, but when properly cooled and arranged with inter-coolers, no lubricating difficulties will be experienced.

The Allen dense air machine, however, presents a very interesting lubricating problem because of the extremely low temperatures encountered in this system. Air is compressed to a pressure of from 250 to 300 pounds, the cylinder being water cooled to carry away a part of the heat of compression. The compressed air then goes to a cooler, where the temperature is lowered as much as possible by water, and then passed into the air expander, which consists of a cylinder on the same shaft as the compressor cylinder. The air is expanded in this cylinder until the temperature drops to a very low point, sometimes reaching 60 degrees below zero. The lubrication of the cylinder under such low temperatures is a very difficult problem, as even most of the natural cold test oils congeal at a few degrees below zero. and to meet these requirements. it is necessary to make an oil from specially selected natural cold test stock. From the expander cylinder the cold air is sent through the refrigeration coils, where the temperature may be as low as 45 degrees below zero.

Efficient oil trapping devices should be installed in all cases, and the oil frequently blown out. If this is done no trouble should be experienced from clogging of the expansion coils. In all expander installations, as in ammonia compression machines, the oil consumption should be cut down as low as possible and still afford proper cylinder lubrication.

PROTECTING IRON FROM CORROSION

In a paper read before the Iron and Steel Institute, Mr. J. N. Friend summarized as follows the results of his researches on the usefulness of paint for protecting ironwork from atmospheric corrosion: 1. The practical value of acceleration tests is very small in the present state of the knowledge on the subject. Reliable results can only be obtained from tests carried out under conditions closely resembling those prevailing in practice. 2. Addition of pigment to oil increases the efficiency of the latter as a protective paint until a maximum is reached. After this, further addition of pigment causes deterioration. The best results are obtainable from paints possessing as high a percentage of good oil as is compatible with good body and any other working property that has to be considered. 3. Linseed oil, on setting, expands by some 3.3 per cent. This is the primary cause of crinkling. Further oxidation causes a decrease in volume, which in time leads to cracking. 4. Linixyn is permeable to moisture. The permeability is reduced by heating in absence of air, the oil increasing in density, viscosity and molecular weight. 5. Polymerized linseed oil affords a better protection than raw oil when used as a paint vehicle. 6. The functions of a pigment are to toughen the film and render it less permeable to water vapour and oxygen. It also reduces the expansion of the oil on setting, and thus minimizes the tendency to crinkle. 7. A thick coat of paint protects the underlying metal more efficiently than a thin coat, provided the coat is not so thick that running or crinkling takes place. 8. The very best results are obtained by multiple coats. Two thin coats are better than one thick one of equal weight. 9. Thinners enable thin coats of paint to be applied. Turpentine leaves a very slight residue behind upon evaporation, but its effect on the efficiency of the paint is small. 10. Other things being equal, the most permanent paints are those containing black or red pigments, since these absorb the shorter rays of light and prevent them from hastening the destructive oxidation of the linoyn by the air. 11. Finer pigments afford more efficient protection than coarse pigments, since they are more thoroughly in contact with the oil. 12. Iron structures should be painted whilst their scale is still on, after loosely-adherent flakes and rust have been scraped off. The paint will last rather longer than if applied to the pickled or sand-blasted surface, and the labor of removing the scale is saved. 13. Experiments with rusty plates are not conclusive but suggest that the rust need not be so carefully removed as is usually thought to be necessary.

IRON CEMENT OR FILLER

By T. H.

In workshops where there is filing and drilling there is usually a lot of fine cast iron in powder to be thrown away, the stuff being a nuisance generally, yet when a joint has to be made or a hole in a casting stopped. filings are conspicuous by their absence. Sufficient finely-sifted stuff passing a 32-in. gauze sieve should be secured. thoroughly dried and kept in an air-tight tin or bottle, and when wanted for use, 80 parts of filings, 2 parts sal-ammoniac, and 1 part flower of sulphur should be very intimately mixed, being careful to finely powder the sal-ammoniac. Immediately before use this mixture should be made into a stiff paste with water and pressed into the cavities, ramming with a piece of wood. In two or three days the material will be hard, and can be filed down level if desired, but it has a slightly brown appearance caused by the formation of oxide or rust.

CATALOGUES

The Ingersoll-Rand Company, have issued a catalogue descriptive of their Imperial type 14 air compressors for belt drives. These compressors are of small size and excellently adapted to many uses around the machine shop and other industrial plants.

"Billy-Isms" is the title of a little booklet recently brough out by the Ingersoll-Rand Company, and is descriptive of the "Little-Tugger" Compact Hoisting Engine, which can be shifted around from place to place and hung anywhere. The hoist is operated by compressed air and is very portable.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 243 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

The Buffalo Forge Company, have issued section No. 100 of their catalogues, descriptive of fans, blowers, and exhausters. This publication takes up the types of fans made, and in addition to giving the various sizes and types manufactured, goes into their manufacture.

The Defender Automatic Regulator Co., St. Louis, Mo., have issued catalog No. 11, descriptive ofthe various lines of power plant regulating apparatus which they manufacture. The publication is unusually complete and is of high value to the power plant operator from the standpoint of efficient operation.

The American Steam Gauge and Valve Manufacturing Company, Boston, have issued booklet descriptive of the American Thompson Improved Indicator. In addition to the descriptive matter on the Indicator itself, a large amount of useful information is contained in this publication relative to the indicating of engines in general.

The Homestead Valve Manufacturing Company. of Homestead, Pa., has added Mr. Charles Nagle to their New York office. Mr. Nagle will call upon the trade within New York and Brooklyn. It has also placed an additional man in their Pittsburg office, in the person of Mr. F. H. Thorn, who has had several years of broad experience in the mechanical engineering field. Mr. Thorn will devote his time exclusively to the plants within the Pittsburgh district.

Wanted representing agents and merchants to sell and represent firm manufacturing Milling Cutters, Twist Drills, Reamers, Lathe Tools, Planer Tools, High Speed Steel and Alloy Tools, and Merchants' Tools. Good terms and discounts for selling or representing offered. Apply Lawton Bros., Woodseats Engineering Works, Sheffield, England.

Western Association of Mechanical and Electrical Engineers

Edmonton District Loop No. 5

This Association would be pleased to receive correspondence from any engineers who would like to associate with us with a view of getting better conditions for the craft in general. We would also be pleased to have communications from any other society or societies of engineers who are endeavoring to secure these conditions. Address all communications to

The Secretary,
Western Association of Mechanical and Electrical Engineers.
P.O. Box 991, Edmonton, Alberta, Canada

The radical but logical departures from standard practice introduced in the steam turbine put on the market some time ago by the Steam Motors Co., of Springfield, Mass., have proven very popular. The Steam Motor, which is the name that the manufacturers decided upon for this machine, differs from the other types of steam turbines in that it is not a complete machine in itself. It is manufactured with one bearing only and when connected to the driven apparatus becomes an integral part of the complete set, making a unit of the two bearing over-all type.

The various advantageous points of the design and particulars of, as well as illustrations covering different applications, are shown in bulletin No. 5, recently issued by the Steam Motors Co.

NEW ELECTRICAL METHODS IN MEDICINE

Electricity, as is well known, plays a large part in the treatment of disease, but its usefulness in diagnosing faults and breakdowns in the human machine is less familiar, except in the case of X-Rays for the detection of fractures and foreign bodies. Several ingenious electrical instruments have been invented and manufactured in Great Britain for giving accurate records of the heart's action and of the temperature of the body. When a current of electricity is passed through the body between the extremities of the limbs, the contraction of the heart alters the strength of the current; by an ingenious arrangement this alteration is made to record itself on a photographic plate. A "cardiogram" is thus secured which gives a diagrammatic account of the heart's action and enables the physician to detect conditions which might escape other means of detection. In taking temperatures, the usual method is to insert a thermometer at intervals and to "chart" the record, drawing straight lines between the points ascertained. With the up-to-date electric method, the record is continuous, showing the slightest variation from minute to minute. Much new light has been thrown on the course of fevers and other diseases by this electrical record, which represents yet another contribution of British scientific and engineering skill to the advancement of the healing art.

AT LEAST TEN CONVERSATIONS NOW PLACED ON A SINGLE WIRE

BY means of Multiplex Telephony apparatus at least ten simultaneous conversations and several telegraph messages may be transmitted over a single copper wire for practically unlimited distances. Demonstrations of the wonders of the new invention were given a party of civic officials and newspaper men at the Strachan avenue Hydro plant at Toronto.

The demonstration is being carried on by the Canadian Independent Telephone Co. of Toronto, which has brought to Canada Dr. Lee DeForest, with a corps of DeForest Radio engineers and Prof. Charles A. Culvert of Beloit College. Major-General George O. Squier, Chief of Staff of the United States Army Signal Corps, is the inventor of "Wired Wireless," and Dr. Lee DeForest the inventor of the appurtenances which made its commercialization possible.

Four on One Wire

Over a single Hydro telephone wire to Dundas four newspapermen carried on conversations at yesterday's demonstration. Every word came clearly and distinctly, and there was no wire noise, such as is encountered on standard connections. On the Bell system there are thirty circuits from Toronto to Hamilton.

According to demonstrators of the "Multiplex Telephony and Telegraphy," with their apparatus nine hundred telephone connections can be made in addition to scores of telegraph connections. It would cost $1,000, they said, to install the apparatus from Toronto to Hamilton—much less when it is manufactured in commercial quantities.

"Viewed from the standpoint of public ownership," say the men in charge at the Hydro plant, "the Province of Ontario now owns several hundred miles of long-distance copper telephone circuits which are used only by the Provincial Hydro-electric officials and employees in the operation of the system.

"These inventions of Squier and DeForest, without interfering with the present use of the line by the Hydro-electric System, can be used to increase the use of these long-distance lines to many times their present capacity and the extra telephone circuits used for public telephone service.

"The Dominion of Canada has recently become owner of the G.N.W. telegraph system and of the Transcontinental telegraph system. These telegraph systems combined represent a very large expenditure of money, and at least part of the Transcontinental is equipped for both telephone and telegraph use. The invention would multiply the possibilities of these lines by at least ten times their present capacity."

BRITISH AUTOMATIC TELEPHONES

Great Britain has shown conspicuous activity in developing the automatic telephone exchange; and the announcement that a sum of £7,000,000 is to be spent on converting the telephone system of London from "manual" to automatic working is proof that the enterprising trials at Leeds and other English towns have been successful. In the automatic telephone the instrument is provided with a rotating dial having numbered depressions near its circumference. To effect a "call" the user places a finger in a certain depression and pulls the dial around to a mechanical stop; this operation is repeated for each figure in the telephone number required. Thereafter the mechanism at the exchange does all the work. It "selects" the line required, rings the bell of the called subscriber and continues ringing it until the receiver is lifted; "holds" the line clear until the conversation is finished and both receivers are hung up; and then disconnects the line. If the called number is engaged a clear signal is given in the calling telephone. The advantage of replacing the fallible exchange operator by almost infallible machinery is so great that the British example is likely to be widely followed, especially in countries where skilled labor is not cheap and plentiful.

Eight real advantages

in equipping water tube boilers, oil stills and superheaters with Key Boiler Equipment Company's

KEY SAFETY HAND-HOLE CAPS

They save time, labor, money, fuel, personal injuries, property damage, consequential loss, and add greater efficiency.

No gaskets required. Over 1,500,000 now in service. Let us send you our descriptive literature.

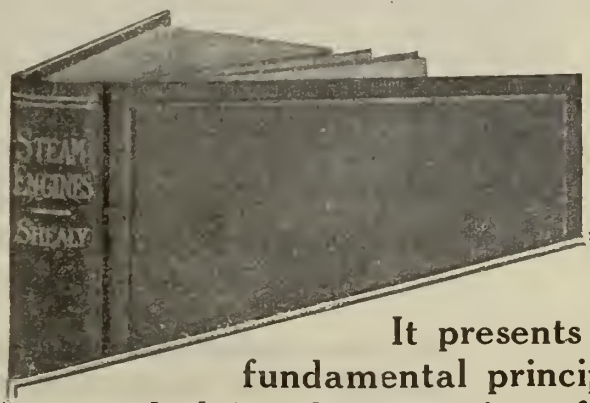
Get This Book



It presents the fundamental principles underlying the operation of the

STEAM ENGINE

The parts dealing with thermodynamic principles are particularly clear and practical.

The treatment of valve gears is especially complete because operating engineers find information on valve gear mechanism so valuable.

Tells about steam engine indicators and indicator diagrams and the proper way to use them.

Gives laws of heat engineering—a plain, straightforward, non-mathematical explanation of the laws of force, work, energy and heat.

And gives other special features too numerous to mention.

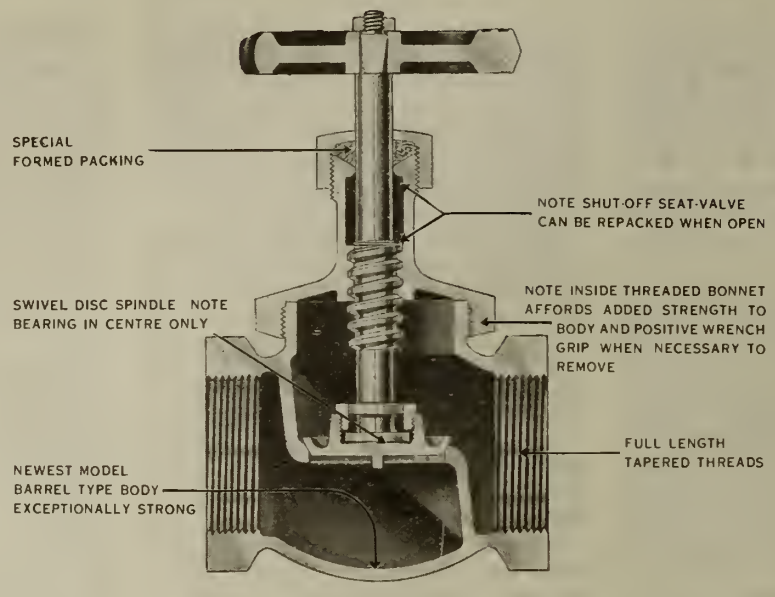
Order from Technical Book Department of "POWER HOUSE," 153 University Ave., Toronto



The Globe Valve Supreme

MUELLER Globe and Angle Valves are standard valves with all of the desirable features of high grade valves. The sectional view above will give you a fair idea of a few of the advantages it offers.

Look at the packing feature—a double seat enables you to re-pack the valve without removing it from the line.

The packing is a feature in itself; a specially formed, properly lubricated braided packing of flax reinforced with a lead core and copper wire strands; filled with graphite, absolutely sure in action; long-wearing and positively leak-proof.

Note the outside threaded bonnet with large hex, giving an added strength to the latest improved barrel type body and a positive wrench grip when necessary to remove.

We will gladly send you a sample valve for trial. Provincial Authorities have passed this valve—allowing a pressure of 175 lbs. We will be especially glad to receive requests from engineers for full particulars and samples of this valve.

Have you received a copy of our new 1919 Catalog "A"—just off the press?

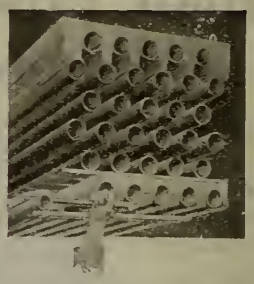
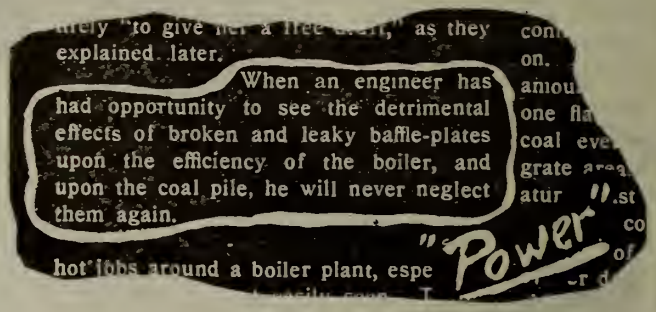
PATENTED, another view of a horizontal water tube boiler, both baffles being made of Betson's Plastic Fire Brick.



How Betson's Plastic Fire Brick is put in place to form horizontal or lengthwise baffles in water tube boilers where it is desired to blow soot from the sides.

MAKE YOUR BAFFLES LEAKLESS
IT IS EASY



explained later.
When an engineer has had opportunity to see the detrimental effects of broken and leaky baffle-plates upon the efficiency of the boiler, and upon the coal pile, he will never neglect them again.
hot lobs around a boiler plant, espe
"Power"

With Betson's Plastic Fire Brick you can make gas-tight permanent baffles, in one piece without joints, so that there is no mortar to crumble away and no bricks or tiles to crack or fall down. Betson's is the only Plastic Fire Brick, and it has made the monolithic baffle-wall practicable.

Gas-tight baffles help you to maintain highest boiler efficiency. They prevent those short circuits that waste coal unnecessarily.

No matter how much the tubes have warped or sprung out of place, baffles of Betson's Plastic Fire Brick will fit exactly,—will be gas-tight,—and remain gas-tight. You can give the baffles any slope or angle desired to meet the conditions of your B & W, Heine, Stirling or any other type of boiler.

One man, without special tools, can make a Betson baffle in the shortest possible time. It will be a better baffle than can be made in any other way. Betson baffles are permanent baffles.

BETSON'S
REG. U.S. TRADE MARK PAT. OFF
PLASTIC FIRE BRICK

Is the ideal refractory for boilers. It has 20 years of practical experience behind it. Beside baffle walls it is used for making solid one-piece furnace linings, front arches, rear arches, etc., in all kinds of boilers and settings. **IT COMES IN YELLOW HEAD BARRELS** in a moist plastic condition ready for use.

Let us quote you on your requirements. Also, ask for our practical catalog,—it will interest you.

Williams "Agrippa" Chain Pipe and Fittings Wrench

THEIR narrow, single jaw, with saw-tempered teeth for file sharpening when worn, gives these wrenches unequaled facility for holding and turning cramped and irregular fittings, flanges, short nipples, etc., etc., because:—

They grip upon surfaces where ordinary tools cannot—"Their grip does not slip."
They do work which tools with broader jaw will not.
They give more and better service than any screw-adjusted wrench made.
They "start" rusted fittings when all else fails—just the service to be logically expected of a fully warranted tool.

Remember, each Chain, like those in our well-known "Vulcan" Wrenches, is "proof-tested" in a standard tension machine to two-thirds of its catalog strength, and is certified. We guarantee absolutely every tool that leaves our factories. 7 sizes for ⅛ to 12″ pipe and fittings.

Why Did We Let Trotzky Go?

THERE was a time when Canada had it in her power to end the war. In the early days of the Russian Revolution a bushy-haired German was taken off a boat at Halifax and interned at Amherst, N.S. He pretended to be a Russian but was known to be in German pay—on his way to push the revolution—British and American Intelligence Officers so informed our authorities. But pressure was brought to bear and the man was finally released. He got to Europe and became the most sinister figure among the Bolsheviki. Largely as a result of his work, Russia dropped out of the war and Germany was able to fight on for eighteen months. That man was Leon Trotzky. His real name was Braunstein.

Why was Trotzky allowed to leave Canada?

Colonel MacLean discusses this question in the June issue of MACLEAN'S MAGAZINE. He tells the story of Trotzky's activities, of his arrest and subsequent release in full detail, tracing the threads of a strange intrigue from Germany to Washington, and Washington to Ottawa. It is a gripping story, the most important inside story of the war.

Other National Features of This Issue

This is an 80-inch 3-ply Heart Brand Belt in a Massachusetts paper mill. It began its service in 1911. It carries 1,100 horse-power. The cost of transmitting a horse-power a week is $.0045.

The Test of Adaptability

For some materials there is no substitute. Such, for instance, is leather for belting. Its superiority for all the major requirements is recognized by transmission experts. The belt shown above, for instance, was transferred from one drive to another—lengthened by splicing, and cut down 2 inches in width—an adaptation that is possible only with leather.

The advantages of leather for transmission are developed to their maximum in Graton & Knight Standardized Series Leather Belts. They are that rare thing in business—a highest-quality line enjoying the largest sales. Do you know of any other brand in any highly competitive field that combines highest grade with biggest sale? Talk that over in your transmission conferences.

A GUIDE BOOK TO REAL ECONOMY IN USE OF PACKINGS

This book explains in detail the importance of using a packing best suited to a particular service. It contains a great deal of information that is valuable to any one who uses or buys packings.

The rapid development of steam engineering has increased steam pressures, added superheat and greatly extended the use of compressed air, all of which creates problems as to what packings should be used to secure the economy of long service under the higher development. This book deals directly with these problems.

We wish to send without charge this helpful book to any one who desires light on the packing question.

ALBERGER MULTI-HEAD WATER HEATER

This is the "ideal heater," because the water is heated as fast as it is drawn. It is the "perfected heater," because an absolute stranger to the costly troubles ordinary heaters so frequently develop.

Transmits 50% More Heat

Than Any Straight Tube Heater

The small, corrugated, pure copper tubes in this Alberger Heater expand into a floating head independent of the cast iron shell, which means that there cannot be trouble from expansion or contraction strain.

An Alberger Multi-Head Heater with corrugated tubes will remain free from scale longer than a heater with plain tubes, because the corrugations promote a scouring effect on the tubes.

You need an Alberger Heater. Therefore ask for catalogue describing both Horizontal and Vertical Types. No obligation whatever.

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

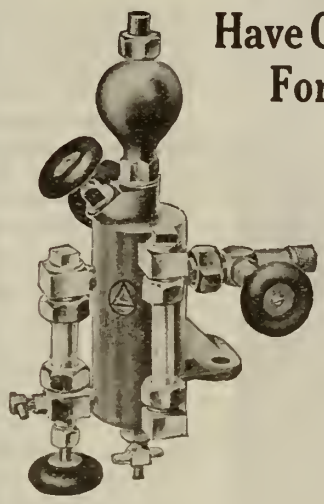
HON. F. G. MACDIARMID, Minister of Public Works and Highways.

W. C. McGHIE, Chairman of Board.

W. A. RIDDELL, M. A. PH. D., Superintendent, Trades & Labour Branch.

Detroit Lubricators

Have Given Satisfaction For Forty Years.



Built in a sufficient variety of styles to lubricate properly every type of steam engine, pump, gas engine, air compressor, etc.

Send to-day for catalog L 1. The information on lubricating devices contained in it will be valuable to you.

THEIR efficiency holds over half the world's trade.

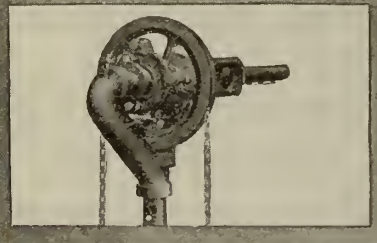
Makers of Stewart Carburetors.

CANADIAN DETROIT LUBRICATOR COMPANY, LTD.

WALKERVILLE, ONT.

No Waste Circulation

THE SANITARY ENGINEER, PLUMBER AND STEAMFITTER OF CANADA was established in 1907. The subscribers represent the most progressive members of the sanitary plumbing and heating trade in Canada. The paper is issued twice monthly, on the first and fifteenth of the month. Circulates in all Provinces of Canada as well as Newfoundland. There is no waste circulation on SANITARY ENGINEER, because subscribers buy the paper for business. The advertising pages are read closely by the largest buyers of sanitary and heating goods in Canada. These men buy for business as well as for private consumption and, therefore, represent the best class of readers. When you advertise in the SANITARY ENGINEER you are assured of an attentive audience, who are looking for information about your goods and your methods of doing business. Cost of advertising is very moderate, indeed, and we will gladly supply detailed information regarding rates and circulation.



The Ledger Tells the Story

Whether or not you open up a formal account with Diamond Soot Blowers when you install them on your boilers, your general ledger soon contains a record of the improved conditions. It appears in such items as decreased coal expense, where if you have been spending $10,000 a month say, you find a falling off of $400 to $800, and in boiler-room pay-roll account, which decreases to the extent of the wages of one or two helpers, a matter of perhaps $200 or $300 per month. General expense is further decreased in a manner not so apparent, but just as tangible, by the reduction of labor turn-over in the boiler-room.

Factory production costs, likewise, are favorably affected, for the output of many departments is absolutely dependent upon their being supplied with definite amounts of steam or mechanical power, when and as needed. When tubes are coated with soot, boilers do not function properly, and their capacity is reduced. Keep the tubes free from soot by rapid, thorough, mechanical means, such as Diamond Soot Blowers, and your boilers can deliver their maximum power.

Diamond Soot Blowers are to-day in use in thousands of industrial plants. They are adapted to and absolutely necessary on all types of boilers. For full information ask for Bulletin 163.

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH

Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

Inquiries from Importers and Dealers Solicited. Send for Catalogue No. 55.

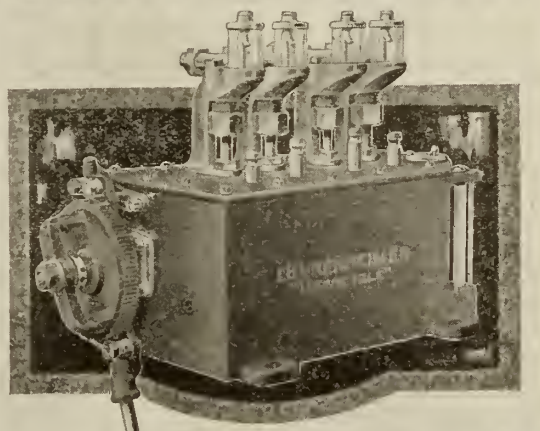
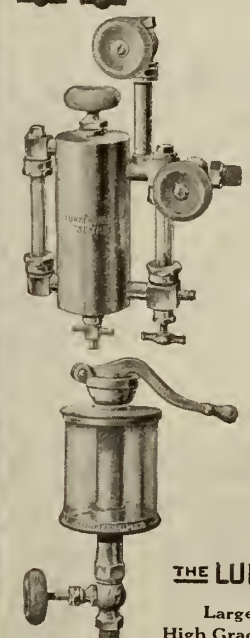
Dependable lubrication



LUNKENHEIMER
CYLINDER LUBRICATORS



are positive in operation, delivering the quantity of oil for which the feed is set—uniformly and without fail.

Their installation on the units of a power plant is assurance of economy both in operation and oil consumption.

The variety of types made includes Mechanical Hydrostatic and Gravity feed, and the Hand Oil Pump is highly satisfactory as an auxiliary when starting or for emergency.

Specify **Lunkenheimer** and insist on their installation. Leading dealers sell them. Booklets No. 526—DC and 572—DC are ready references on lubricator equipment. Copies of both at your request.

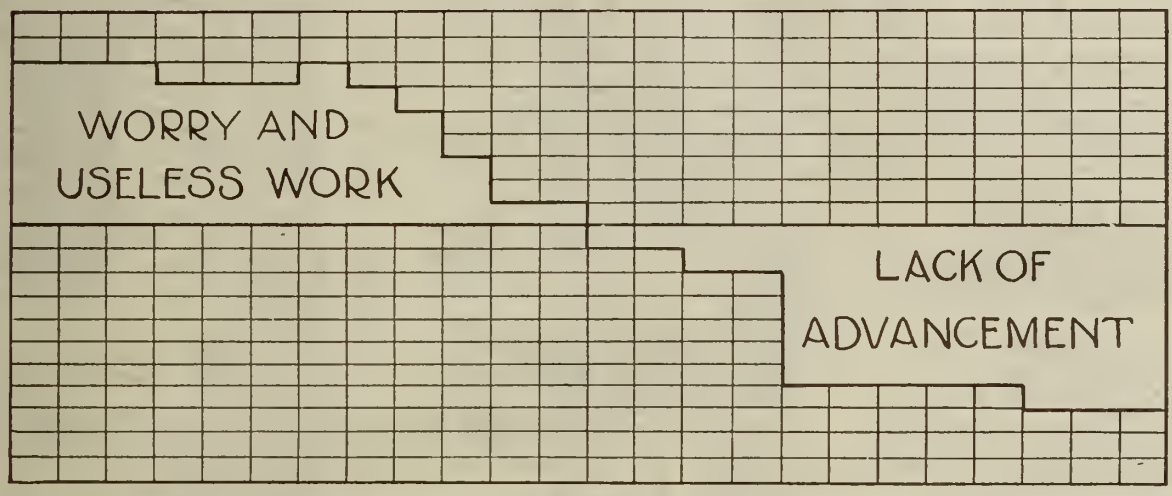
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

UEHLING WASTE METER

COMBINED

CO_2 AND TEMPERATURE RECORDER

Record of CO2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The **Uehling CO_2 Recorder** makes a complete 24 hr. record of your combustion efficiency and the **CO2 indicator at the Boiler Front** holds the fireman responsible.

Get more **Steam** per pound of **Coal** and reduce your annual fuel consumption.

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.

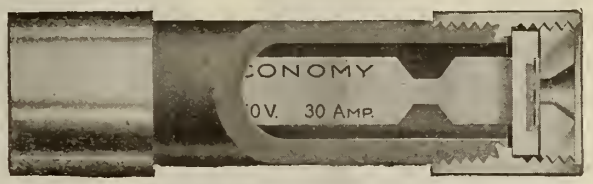
CO2 Indicator for Boiler Front

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

Uehling Instrument Company

2008 Empire Building New York City



ECONOMY Renewable FUSES

stand between the user and unnecessary expense. An inexpensive "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency. The resultant saving approximates 80% of annual fuse maintenance costs as compared with the use of one-time fuses.

This economy is effected with safety, as years of use have conclusively proven that Economy Fuses are all that could be desired as regards accuracy of rating and all-around efficiency.

They cost least and serve best.

If you are among the thousands of Economy users, you already know this, If not, *try* them and you soon *will* know.

Write for Catalog 24

This book should be in the hands of every pump user. A postal will bring your copy promptly

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compress

Marsh and American Pumps are especially adapted for long, hard service because are *extra heavy* in design and of *extremely rigid construction*. Every unit is built as strong to withstand 24-hour-a-day service and to stand up under any unforeseen st which may be placed upon it. Piston rods on the steam pumps are extra large made of solid bronze. The water ends are equipped with heavy cast bronze remov bushings.

This superior construction not only insures continuous and satisfactory operation, practically *eliminates expensive shut-downs*. Marsh and American Pumps are the duct of over 25 years' experience in the design and construction of high grade pum machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both si and double suction types which are designed for heads up to 125 feet. They equipped with wide ring oiled bearings and the single suction type has overhan casing enabling the discharge to be taken at any angle desired.

OIL FILTRATION MEANS ECONOMY

A BOWSER Filtering and circulating system, supplies the National Cash Register Co.'s power plant.

Hundreds of installations and repeat orders from among the largest manufacturing establishments in this country and abroad are a testimonial to their general excellence.

If you are interested in reducing your consumption of lubricating oils, the installation of Bowser oil handling, distributing and storage devices will point the way.

No plant too large, none too small for which Bowser has not suitable equipment; none in which Bowser will not bring about a material saving in lubricant.

Users of Bowser equipment include many of the largest manufacturing establishments in this country and abroad.

Write us. Our data on lubrication will interest you.

KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Boiler Room Efficiency Instruments

NO MORE GUESSING IN YOUR BOILER ROOM
THE DEFENDER SYSTEM (READS)

Draft, Temperature and CO_2 on each Boiler. Determine the Draft over the fire and at the last pass of the Boiler and the drop in Draft through the Boiler—that gives the highest percentage of CO_2 in the Flue Gas and the lowest Flue Gas Temperature.

This gives the highest Boiler and Furnace Efficiency. The Defender Catalogue No. 10, which is just off the press, shows a very complete line and price list of Combustion Appliances and Damper Regulators for the Boiler Room.

The Defender Automatic Regulator Co., 709 Pine St., St. Louis, Mo., U.S.A.

"Beaver" Check Valve.
Bronze.

The valve and seat can be furnished metal to metal regrinding, or with renewable copper disc. The seats are renewable and are fitted with set screws to prevent their working loose when the valve is in operation.

Particular attention is called to our improved joint between the body and yoke, the machined faces of the double spigot preventing any possibility of the gasket blowing out.

The stuffing box gland being made of bronze offers a non-corrosive surface for the stem and also prevents the gland breaking when the stuffing box is being packed.

Beaver valves have full area throughout.

Designed for a working steam pressure of 250 lbs. per sq. inch and are subjected to a hydraulic test of 500 lbs. per sq. inch before leaving our factory.

Write for full particulars.

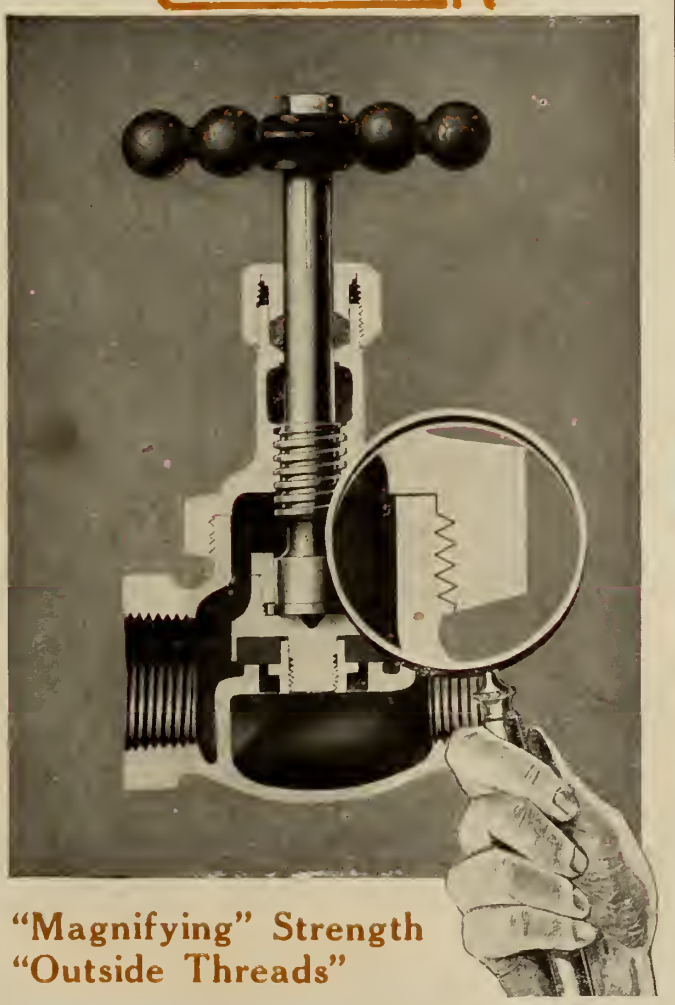
COMPODISK

PENBERTHY



"Magnifying" Strength
"Outside Threads"

PENBERTHY

All Penberthy Values

are designed with outside threads on the bonnet end of valve body. When tightening bonnet down to place this construction prevents spreading or enlarging bonnet end of body, causing a loose fitting and unsafe valve. The threads, being on the outside, are immune from the corrosive action of steam and water, thus preventing freezing of bonnet and body together and eliminating all strains.

Architects and Consulting Engineers

who appreciate quality and efficiency in brass valves will find the Penberthy line specially suitable for conditions that require something better than the ordinary valve on the market.

IMPERIAL

Lubricants

FREE---BUT PERHAPS WORTH HUNDREDS OF DOLLARS TO YOU

KNOWLEDGE is power. The knowledge that your machinery is 100% efficient is a potent factor in the success of your industry and this mechanical efficiency is very largely a matter of lubrication.

Imperial Lubrication Engineers are entirely at your service. Free of charge and without putting you under any obligation, they will gladly give you the benefit of their expert knowledge. They have made a close study of the lubricating needs of all types of machinery under service conditions. They offer you, therefore, a highly specialized service.

The vital necessity of correct lubrication will prompt you to appreciate this service. Your own Engineer realizes the importance of correct lubrication and will welcome a consultation. You will have the added satisfaction of knowing that you have taken every precaution to insure maximum service from your power plant.

There is one other point. You may be using the right lubricants now—lubricants which are correctly graded and accurately formulated for all types of machinery—but you may not be getting the most out of those lubricants. Imperial Lubrication Engineers will see that you are not only using the correct lubricant, but using the right one for every bearing and using each in the proper way.

Hoyt Babbitts

SAVE POWER

Reduce friction and save power by using a good quality of babbitt metal in your plant. Hoyt Babbitts are in universal use. They have won their way through matchless **quality.**

HOYT FROST KING—an all-round Babbitt. The use of "Frost King" invariably reduces babbitt expenses; it's efficiency and splendid performance under heavy duty has made it an international favorite. HOYT'S NICKEL GENUINE—for heavy duty and high-speed work you need a tough and durable babbitt metal, and one that runs cool. Use Nickel Genuine specially designed for use in marine engines, gas and gasoline engines. If unable to get from your dealer, send to us for 25-lb. shipment.

Frost King

Nickel Genuine

All elements entering into our mixtures are carefully refined and put together in such proportions and in such relation to each other that the best possible alloy is secured for the work for which it is designed.

When you use Hoyt Metals you may be assured of best possible results.

STEEL PLATE WORK

WE have made a success of building Steel Plate Work by specializing in it.
The recent extensions to our shops have placed us in a better position than ever before to do this work. Our facilities in every department have materially increased—we have the men, the equipment, and the experience to turn out this special work as it should be.
We design and build any size of:—

Conveyors and Elevators
Smoke Breechings
Steel Stacks
Spark Arresters
Steel Buckets
Steel Tanks
Storage Bins
Cookers and Digesters
Steel Gas Mains
Refuse Burners

Before you buy anything along these lines, send us your sketch and let us quote.

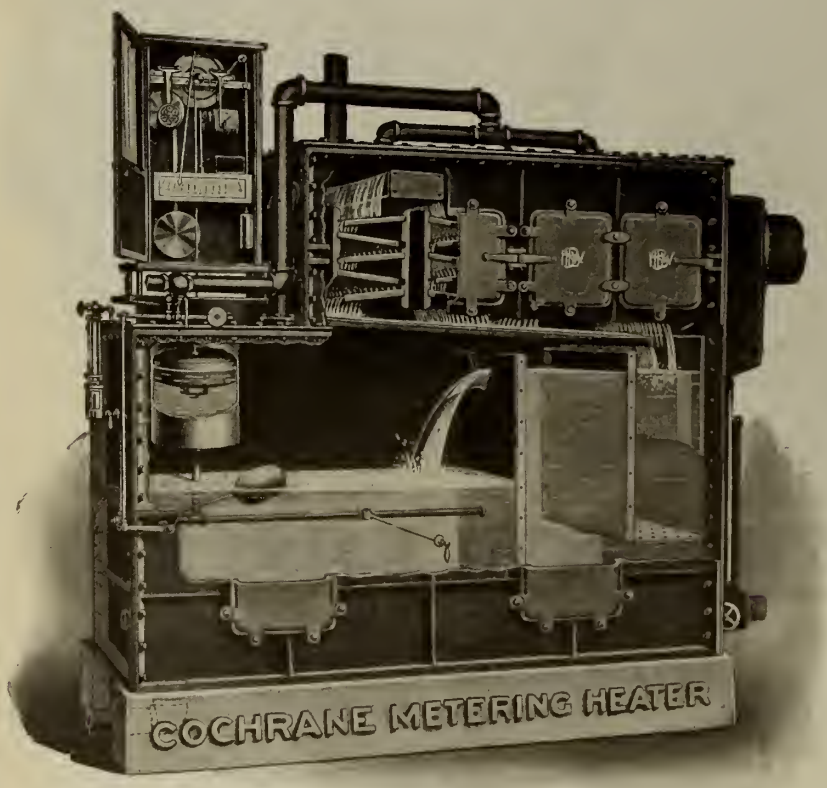
Finding and Stopping Waste in Modern Boiler Rooms



KEEPING BOOKS WITH THE BOILER

How many pounds of water are your boilers evaporating per pound of coal?

Are they doing 6 or 7 pounds, or just a shade better, or are they up to the top notch, say 10 or 11 pounds of water evaporated per pound of combustible?

The Cochrane Metering Heater tells how much you are getting for your money

Send for Catalogue No. 820

Other Cochrane aids to boiler room economy include open feed water heaters, steam stack and cut-out valve heaters and receivers, metering heaters, and independent meters. Sorge-Cochrane hot process water softeners, steam and oil separators, and multiport back pressure, atmospheric relief, flow and check valves.

Head Office: Toronto. Sales Offices: Montreal, Quebec, Halifax, Sydney, St. John, Ottawa, Cobalt, South Porcupine, London, Winnipeg, Calgary, Edmonton, Nelson, Vancouver and Victoria.

Superb Tone

Lunkenheimer Whistles

"you hear them everywhere"

Their tone is distinct, far-reaching, clear and harmonious.

They are economical because the orifice through which the steam passes is so shaped and located that a maximum volume of sound is obtained with a minimum expenditure of steam.

A variety of types for use on Factories, Locomotives, Steamships, Motor Boats, Steam Shovels, Traction Engines, Signal Systems, etc.

Specify **Lunkenheimer** and insist on their installation. Your local dealer can furnish them; if not, write us. Write for Whistle Booklet No. 520-DC.

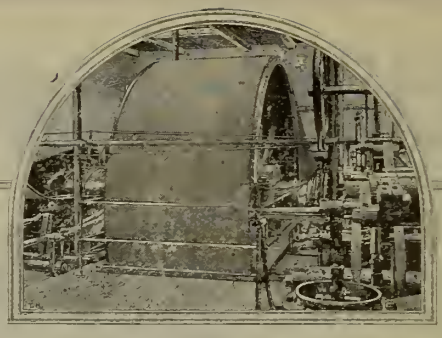
21-13-43



This is an 80-inch 3-ply Heart Brand Belt in a Massachusetts paper mill. It began its service in 1911. It carries 1,100 horsepower. The cost of transmitting a horsepower a week is $.0045.

THE TEST OF ADAPTABILITY

For some materials there is no substitute. Such, for instance is leather for belting. Its superiority for all the major requirements is recognized by transmission experts. The belt shown above, for instance, was transferred from one drive to another—lengthened by splicing, and cut down 2 inches in width—an adaptation that is possible only with leather.

The advantages of leather for transmission are developed to their maximum in Graton & Knight Standardized Series Leather Belts.

Write for booklet on standardization as applied to belting.

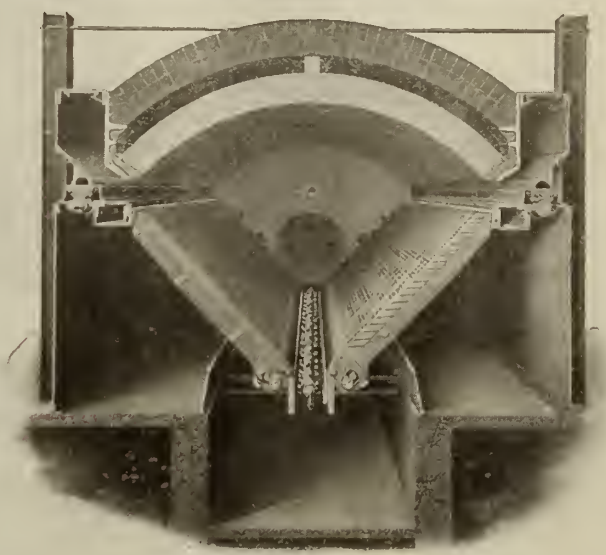
MURPHY AUTOMATIC FURNACES



For Any Boiler
50 h.p. and Up

Any boiler from 50 h.p. and up, can be equipped with the MURPHY FURNACE. The ***smaller plant*** can therefore enjoy all the economical advantages of fuel and labor savings ***without resorting*** to forced draft.

To-day over ***6000 boilers*** are fired by MURPHY FURNACES. You will find them used in nearly every branch of the industry from hospital to industrial and central station service. MURPHY FURNACES "burn any fuel that has heat in it." They double the output of the plant "without one penny for draft."

Our Catalogue "HM 6" shows how MURPHY FURNACES can be installed under any type of boiler—50 h.p. and up.

For information on RILEY UNDERFEED STOKERS for large boilers see June 5th advertisement or send for RILEY STOKER Catalog "HR-6."

MECHANICAL REFRIGERATION

SAVES MONEY :-: HELPS BUSINESS

"We wish to express our satisfaction with your plant, which in the past several years has saved not only money and labor, but proved a business asset as well," writes one of our customers.

Here is the whole story in a few words. No addition to your business offers more certain returns on the investment than MECHANICAL REFRIGERATION.

If your business is lagging, it can be improved by the use of MECHANICAL REFRIGERATION. If your business is good, it can be made better by installing a YORK REFRIGERATING PLANT.

Write to-day for information and prices.

Preventers of Heat Waste

That's what Nonpareil Insulating Brick are. Built into the walls, arches, bottoms and doors of furnaces, boiler settings, ovens, etc., one 4½-inch course will save 60% or more of the large quantity of heat ordinarily lost through the brick work. And the saving in fuel which results will pay for the brick in a year or less.

Let the hottest flame you can find play against the face of a Nonpareil Insulating Brick. Long after the surface has become white hot, you will be able to hold your hand against the opposite side without discomfort. Now try the same experiment with a fire brick or common red brick, and note the difference.

Nonpareil Insulating Brick

For Furnaces, Boiler Settings, Ovens, Etc.

Nonpareil Insulating Brick are composed principally of diatomaceous earth, a peculiar cellular material of high natural insulating value. Each of its minute cells contains "dead" air. The ground earth is mixed with granulated cork, molded into brick form, and then fired. The cork is thus burned out, thereby adding to the number of "dead" air spaces, and materially increasing the heat insulating efficiency of the finished Nonpareil Brick.

These Bricks are especially suitable for the insulation of high temperature equipment. They have an ultimate crushing strength of 10 ton per square foot. The finished brick form makes them easy to handle and install. Furthermore, Nonpareil Brick are so light, 1.6 pounds each for the 9 x 4½ x 2½ inch size, that when substituted for an equal amount of common brick, the total weight of the insulated structure is reduced materially.

It will interest you to know about the savings that Nonpareil Insulating Brick would effect in your own plant. Copies of the booklets, "Good Furnaces Made Better" and "Saving Fuel," together with a large sample will be sent, free of charge, on request.

Nonpareil High Pressure Covering not affected by water.

Nonpareil High Pressure Covering

For high pressure and superheated steam lines, underground heating systems, boilers, breechings and heated surfaces.

In these days of high fuel and labor prices, the question is not, "Shall I insulate my steam line?" but rather, "What covering will save the most coal?" The answer, as careful investigation will show, is Nonpareil High Pressure Covering.

This—"The Steam Covering That's Different"—is composed principally of diatomaceous earth (kieselguhr)—a light cellular substance that is practically pure silica and an excellent nonconductor of heat. The covering is not only an efficient heat insulator, but will withstand relatively high temperatures without calcining or disintegrating. Furthermore, it is not affected by water and will stand repeated wetting and drying without injury. It is furnished in sectional, block and plastic cement form, making it easy to apply. The bound book, "Nonpareil High Pressure Covering," is worth asking for. It shows how you can determine your radiation losses, also overcome same.

ARMSTRONG CORK & INSULATION COMPANY

LIMITED

Manufacturing All Kinds of Special Shapes in Refractories

Remember, we are making all our own blocks and making a specialty of special shapes.

We are using a high grade fire clay, which is the factor of supreme importance in all processes of manufacture. Our burners are experts. When you are in the market be sure and write us as we know you will find our proposition interesting.

Our stoker arches are designed to promote combustion and give longer life.

Our door arches and jambs are made to withstand the strong-armed boy with the slice bar.

Our side wall blocks are made to eliminate the many joints that clinkers stick to, when ordinary fire brick is used. They give longer life and reduce air leaks to a minimum.

We designed these arches and blocks so that any handy man could replace same in half the time that it takes to repair a standard fire brick job.

Remember, Gates' blocks means cutting your cost of upkeep and fuel bills.

We specialize in all kinds of POWER PLANT BRICK WORK

Call on our engineers at any time for information you may require; their services are offered to you without obligation.

Inside Facts About the Dunham Radiator Trap

The Dunham Radiator Trap is distinctive in the simplicity of its construction. It consists of two major parts, a body and a cover. In the cover the operating member, the Dunham Thermostatic Disc, is securely placed. It has an exceptionally large valve opening, there are no loose parts in the path of flow, no sliding contacts, nothing to gum up, and no guide or pin to obstruct the valve opening.

The position and design of the valve is such that it is self-cleaning; the action of the disc is positive, and the valve seats squarely like a globe valve, the tightest of all types of valves. All of its working parts are made of non-corrosive material of the best quality, the workmanship is of the highest order, all parts being made to exacting standards and every finished article given individual working tests.

"We Install a Jenkins Bros.' Valve with a Feeling of Confidence"

THIS is the actual statement of a prominent engineer, just after he had installed a genuine Jenkins Bros'. Valve in a troublesome line.

"That extra metal that Jenkins puts in his valves is just where it's most needed and I've never known a 'Jenkins' to break down even on a line where the pressure and strain is greatest."

Over fifty years of valve making is behind genuine Jenkins Bros'. Valves. They are the result of a thorough understanding of valve requirements and valve uses.

Jenkins Bros.' Valves are of all types and sizes for all uses, made of brass, iron and cast steel. They are distinguished from their imitations by the "Diamond Mark" cast on the body.

Look for it—demand it.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

ANNOUNCING

A New Emergency Power Plant

Medium and high speed Sterling gasoline engines (which have held world's marine speed records for eight years) have been adapted for driving centrifugal pumps and electric generators. They are being used by many prominent pump manufacturers, coupled to Underwriters fire pumps, and are installed in townships, villages, municipalities, department stores and manufacturing plants for fire protection. They are also utilized for emergency generator drives. The motors are admirable for either pump or generator operation as they develop rated power at 800, 1,000, 1,200 and 1,400 R.P.M. The construction is in 4, 6 and 8 cylinder units, 10 to 300 H.P.

Numerous units are employed in the United States and Canada. They are equipped for instantaneous starting for any emergency and will always furnish dependable power until the emergency will have passed.

THE SCOOP CONVEYOR

The Scoop Conveyor Keeps Equipment Moving

Two or More Scoop Conveyors Make a Flexible Arrangement

Unloading Hopper Bottom Cars Direct Into Trucks with a Scoop Conveyor

DOES THE WORK OF FROM 6 TO 12 MEN

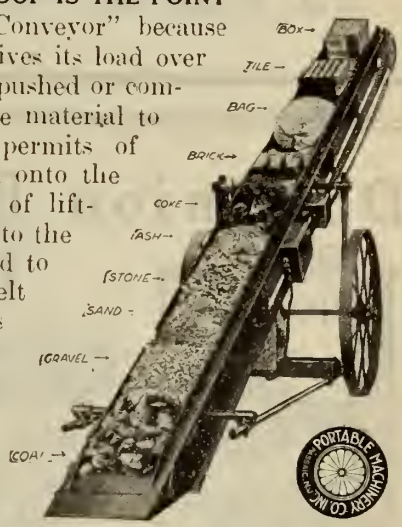
It has proven to be one of the greatest labor and time savers in storing and reclaiming, in loading and unloading cars, trucks and wagons. It keeps equipment moving. Enables men to work faster and easier. Eliminates much shovel and wheelbarrow work. Does three to five days' work in one.

OVER 1000 USERS

The Scoop Conveyor has been adopted by over 1,000 leading American manufacturers, contractors and coal dealers because it is durable, compact, easily moved around and low in cost. About one-half of our sales are "repeat orders."

THE SCOOP IS THE POINT

It is called "Scoop Conveyor" because the carrying belt receives its load over a scoop which can be pushed or completely buried into the material to be conveyed. This permits of scraping the material onto the carrying belt instead of lifting it by shovelfuls into the receiving hoppers fitted to ordinary portable belt conveyors and results in a saving of fifty per cent. of the labor in feeding.



Write For Literature

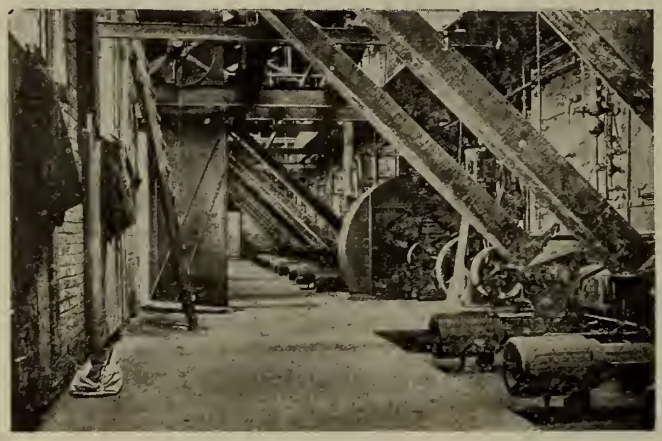
PORTABLE MACHINERY CO.
PASSAIC, N.J.

Sand, Gravel, Coal, etc., Easily Loaded with a Scoop Conveyor

Unloading Hopper Bottom Cars with a Scoop Conveyor. No Track Hopper or Pit Is Necessary

Down Goes Fuel Cost!

15 to 25 per cent



This is a result that is quickly noticed, following the installation of the

Jones Underfeed Automatic Stoker

The "Jones" feeds fuel better and more economically than the best of firemen. It maintains a uniform steam pressure and responds instantly to varying demands for steam.

The "Jones" construction means durability. No parts more in contact with the fire—and loss of fuel through grates is impossible because there are none.

May we send you full facts and figures re the saving effected by this modern way of stoking?

Jones Underfeed Stoker Co.

GREEN'S

HI-EFFICIENCY HI-SPEED

RADIAL FLOW FANS

have the following advantages

1. They require approximately 20% less horsepower than any other fan.
2. They are so designed that the rotor and bearings may be easily inspected without changing the alignment or dismantling the flue work.
3. They run at speeds best suited for direct connection to turbines or motors and are also suitable for gear or belt drive.
4. Any blow back through the fan inlet or dead space on the fan wheel is impossible due to the design of the rotor and housing.

Our engineers will be glad to furnish more complete information in regard to these fans to cover your individual requirements.

SARNIA :-: CANADA

There's a Big Waste in Little Leaks

Do you know that a one-tenth inch pipe-joint leak at 150 lbs. pressure will waste steam in a year at a cost to-day of approximately $825? Figure it out for yourself. Leak one-tenth inch; pressure 150 lbs.; 9 lbs. steam per lb. coal; coal $5.50 ton; 10 hours per day; 300 days per year.

And it's such an unpatriotic waste in these days of coal conservation—such a needless and careless waste at any time—for the leak can be stopped in a few minutes' time with a

YARWAY PIPE-JOINT CLAMP

Formerly the SIMPLEX

More than 13,000 leaks have been stopped since this effective clamp was first placed on the market. Millions of dollars have been saved. The saving in coal can only be guessed.

The Yarway (formerly the Simplex) can be attached in a few minutes by any workman. The principle can be seen from the illustration shown here.

If there is a pipe-joint leak in any of your lines, tell us the size and we will send you a Yarway for 30 days' trial. Instead of returning it, you will probably be as enthusiastic over its success as the man who said of a Yarway Clamp, "It's worth its weight in gold."

The Publisher's Page

TORONTO JUNE 20, 1919

The Canadian Association of Stationary Engineers

The Power House,
Toronto.

Hamilton, May 29th, 1919

Dear Sirs:—

It seems an age since I last wrote to you, but I have really been very busy owing to the strenuous pre-convention duties associated with the office of Secretary of the C.A.S.E.

I am enclosing my renewal POWER HOUSE subscription fee of $1.00. It is well worth twice or three times that amount, but as $1.00 is your price, here goes. The engineers certainly appreciate this exceptional price, which we understand cannot continue for long.

I am greatly pleased and amazed at the phenomenal success that has attended the publishing of POWER HOUSE, especially since it has been issued in semi-monthly form.

The excellent editorial contributions, plant articles, new equipment information, question box, etc., etc., have been of the highest order, and to my personal knowledge have been of great benefit to your readers.

MR. JOHN HALE
Secretary, Canadian Association Stationary Engineers.

The spendid industrial representation in the advertising pages is worthy of special notice—the educational nature of the advertisements being particularly valuable.

POWER HOUSE enjoys the position of Leadership in power plant efficiency, in equipment and service. Through it we have kept abreast of the forward movement in engineering and scientific matters associated with the power plant. Its policy is understood by the junior engineer, and to him is POWER HOUSE particularly valuable. It is an inspiration. It is preparing the engineer for the test which will come in 1920.

Each issue is therefore looked forward to with great anticipation, and from my personal knowledge, I believe it is studied from cover to cover.

I hope to have the pleasure of meeting you at the Brantford Convention, which gives promise of being the best we have ever had.

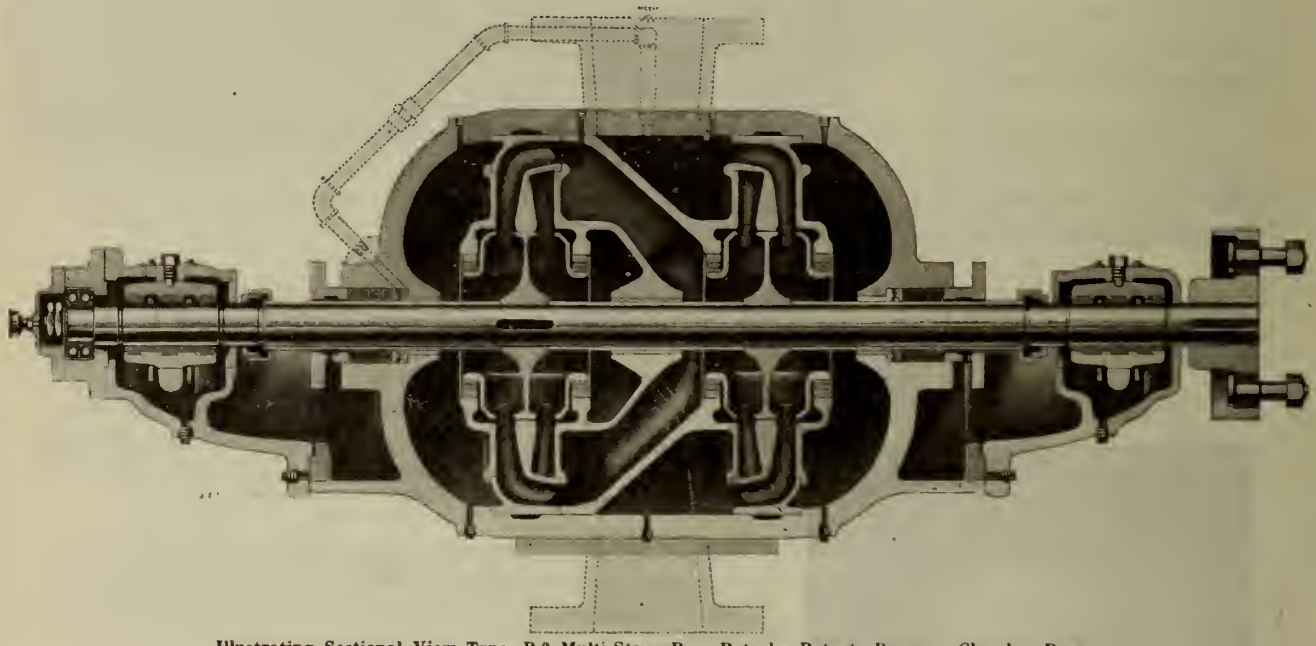
Yours sincerely,

JOHN HALE,
Secretary, C.A.S.E.

REES RoTURBo

Pumping Machinery

Is in use all over the World in Waterworks, Mines, Power Stations, Irrigation Works, Pulp and Paper Mills, Salt, Chemical and General Industrial Plants where highest efficiency, reliability and the best class of Engineering are demanded.



Illustrating Sectional View Type, B.2 Multi-Stage Rees Roturbo Patent Pressure Chamber Pump.

REES RoTURBo Pumps provide a high and sustained efficiency over a wide range of duties. This means a very noticeable saving in power costs.

The Self-Regulating feature of RoTURBo design is responsible for this saving, and this same feature protects your Prime Mover from overloads on a decreased pressure head, eliminating expensive delays and costly repairs.

Our RoTURBo Pump and Condenser Catalogues, full of valuable information, are yours for the asking.

POWER HOUSE

Established 1907

Published Semi-monthly

BRANTFORD The Scene of the Annual Convention C.A.S.E.

IN choosing Brantford as the convention city for 1919, the Canadian Association of Stationary Engineers have selected one of the industrial centres of the Dominion, and a city noted for its many historical associations.

The industries located in Brantford number upwards of one hundred, and include some of the largest and best known in the Empire. The Verity Plow Works, the Waterous Engine Works, the Cordage Co., and a firm making stoves and furnaces, are all representative of the manufacturing ability displayed in the community.

Historical

Historically, Brantford dates back to the time of the Indian, and the name of the city, and the statue of Joseph Brant, the Mohawk chief, in Victoria Park, are indicative of the city's origin. The Indian chief and the early white settlers lived together in peace and amity on the banks of the Grand River, near the ford, which formed a part of the well-known route of the Six Nations settlement to London.

Most of the early settlers were U. S. Loyalists, and by 1818, twelve families had gathered in the small community, which boasted two taverns, a blacksmith shop, general store, and grist mill. The settlers coming into this part of the country, which was practically an unbroken forest, had many hardships to bear and difficulties to overcome. He usually journeyed with his provisions, beds and cooking utensils on one horse, his wife and children on another. His cabin was made of round logs notched at the ends, and the chinks filled with clay. The door was made of split clap-boards hung on wooden hinges, and the flintlock rifle with powder horn and bullet pouch was always conveniently close at hand over the door. The wide fireplace was fashioned of rough stone, and its chimney of split sticks and clay. Homemade furniture was built by hand, while the spinning wheel, now an ornament, was sent swiftly whirring by the busy housewife.

Brantford obtained its present name in 1826, when the naming of the community, now numbering about one hundred settlers, was discussed, and several names were proposed. The memory of the Mohawk warrior who first designated the crossing over the Grand River rose in their minds and prompted them to christen the place Brant's Ford, which time curtailed to Brantford.

ALEXANDER GRAHAM BELL
the inventor of the telephone.

It is a city of happy homes, where industrial disputes are rare and short-lived. Significant of this may be recorded the fact that when the Waterous Engine Works found it necessary to erect a larger establishment some years ago, instead of importing some dignitary, they placed the trowel in the hand of their oldest employee, John Morice, who laid the corner-stone truly and well. Such is the spirit of the city. It is owing to this spirit that Brantford has achieved her present renown as a manufacturing city, and the names of her manufacturers are widely known throughout the Dominion.

The growth of a community depends on the transportation facilities offered by the railroads and other public carriers. Brantford's railroad connections are unusually favorable. The Grand Trunk built lines to Harrisburg and Tillsonburg, and later found it to their advantage to divert their main line so as to pass through the city. The T. H. and B. gives excellent connections with Toronto, Hamilton and Buffalo, while radial lines also connect Brantford with Hamilton and Galt.

From the time Brantford's first little frame church was endowed by an Indian chief, the religious side of the community has expanded, until nearly every denomination is represented

Brantford has every reason to be proud of her educational institutions, which have grown from a frame building, first to be erected on the market square, until nine public schools, one

manual training school, and the new Collegiate Institute are required to keep abreast of the city's educational requirements. The Brantford Collegiate Institute, recently erected on the site of the Young Ladies' College, is one of the finest buildings in the city. The Provisional School for the Blind, opened in 1872, has been the means of alleviating much of the distress of those suffering from this affliction. The ample grounds, together with the educational facilities and comforts provided, are commensurate with the importance of the institution.

Prior to 1848, Brantford had no hospital. In that year the city was visited by a severe epidemic of cholera, which swept over the country, and temporary hospitals had to be erected. The John H. Stratford Hospital, originally the gift of Mr. Stratford, now expanded into the city hospital, and the Brant Sanitarium, on a site commanding an excellent view of the city, the gift of E. S. Cockshutt, promote the welfare and health of the citizens.

MOHAWK CHURCH

The Story of the Telephone

When, in 1876, a goodly handful of residents of Brantford heard the voices of a trio of singers over a telephone line which had its terminus in Tutela Heights, the home of Alexander Melville Bell, father of Alexander Graham Bell, the inventor of the telephone, it was accounted one of the wonders of the age, yet to-day, when messages are exchanged between New York and San Francisco, when Boston hears Los Angeles celebrating, or the sound of the surf at Seal Rocks, it is dismissed as one of the day's normal happenings. The telephone is accepted as one of the necessary adjuncts of the business, professional, industrial, or social life of the day.

Joy and sorrow, business and pleasure —the telephone wires carry them all, yet prior to the year 1876, when in Brantford the first telephone message was sent over a real telegraph line, all messages had to be carried by hand. The telegraph had been invented by Morse in 1835, and thus messages could be transmitted over by wire through electric energy. These messages, however, had none of the personal touch. That the conveying of the actual intonation of a speaker with all the mannerism of inflection was made an actual accomplishment, is due entirely to two men— Alexander Melville Bell and Alexander Graham Bell, his son. The former was a noted master of elocution and the inventor of a new theory of articulation, by which all audible sounds could be reduced to signs translatable by any person instructed in the symbols. The son, also versed in the science of speech, when but a young man became possessed with the idea of teaching deaf mutes to speak, being the first, at least in England, to do this. Later, Alexander Graham Bell accepted a position teaching deaf mutes in America, the father accompanying the son and settling at Tutela Heights, Brantford. The son, during the school session, lived in Boston, spending the summer vacation and Christmas holidays at the parental home in Brantford.

To carry out his plan of teaching deaf mutes to speak, Alexander Graham Bell secured a phonautograph, a hollow cylinder with one end covered with a membrane, to which was attached a long bristle stylus. As one talked into the other end the bristle, because of the vibration of the membrane, was made to write a waving line on a revolving cylinder of smoked glass placed before it. These lines were the outline of the sounds uttered.

At this time he was also work- experimentally upon multiple telegraphy, whereby he hoped messages could be sent along the same line simultaneously without confusion, by employing musical signals of definite pitch. These researches culminated in the invention in Brantford, in 1874, of what is now known as the harp telephone, the ancestor of the speaking telephone.

It struck the young scientist, while at work with the phonautograph, how simliar that instrument was to the human ear, and how perfect a mechanism the human ear was. The suggestion came to him, after studying the ear's mechansim, that a phonautograph modelled after a human ear would be extremely effective for his purpose, and accordingly, on the advice of an eminent aurist, he secured a human ear. This he made into a phonautograph, taking a single fibre of hay as a stylus. The waves of sound as he talked into the ear, vibrating the delicate membrane of the tympanum, caused the bone to move and the wisp of hay to record the movements of the diaphragm upon a piece of smoked glass. The thought entered his mind, as he watched the tracings, that if the tympanum of the ear, so delicate, could move relatively so massive a structure as that of the bones of the ear, why could not a piece of iron be caused to vibrate in front of an electro-magnet by means of a larger and thicker membrane?

Thus was the telephone conceived in the Bell homestead on Tutela Heights. The significance of the movements of the membrane did not escape the young scientist, who realized that at last he had solved the problem upon which he

VICTORIA PARK IN THE CENTRE OF THE CITY.

MOHAWK LAKE, BRANTFORD, A FAVORITE PICNIC GROUND.

had been working for some years. He converted the harp telephone into a membrane-speaking telephone modelled after the human ear by attaching one of the reeds of the harp telephone to a stretched membrane, and thus forcing it to copy the movements of the air during the utterances of a sound which caused it to vibrate. And the telephone was an actuality.

But though the telephone was a reality, it was by no means perfect. He continued his experiments, and by the following summer, while again visiting at his home on Tutela Heights, he had so far advanced that he was able to write out the patent specifications during the month of September, 1875. These patents were largely based upon the liquid spark arrester which he had invented and made in Brantford during that summer vacation. He found difficulty in working the multiple telegraph apparatus on account of the spark which appeared between the contact point of the transmitter when the circuit was broken. This he overcame by bridging the gap with water and by dipping one of the conducting wires very slightly into the water. The wire was adjustable up and down to regulate the amount of resistance introduced when the main circuit was broken.

This invention was of more than ordinary importance because, in drafting his specifications, he laid stress upon the variable resistance apparatus, upon which the famous Government suit was won by him in later years.

The following year the first messages were sent over a real telegraph line, all experiments hitherto being conducted by means of wires in coils, kept in one building. In 1876 the inventor again spent his summer holidays at Tutela Heights. Through the kindness of the Dominion Telegraph Company of Canada, the local chief being Mr. W. H. Griffin, with Ewen Cameron, still residing here, as a member of the staff, its lines were placed at his disposal for experiments. On August 10, or close to that day, 1876, experiments were made on the telegraph line between Brantford and Paris, which had two very important results. For the first time a message was transmitted by telephone over a real telegraph line, and the proper relation of the parts of a telephone to each other was discovered, enabling its use upon a long line. The receiver of the telephone was in Paris, the transmitter in Brantford, and the battery which supplied the motor power, in Toronto. The young inventor had made arrangements with his uncle, the late Prof. David C. Bell, then a resident of Brantford, to take charge of the transmitting station, as his father had stated that he would not be able to be present. Persons were to sing, talk or recite into the transmitting instrument in Brantford, while he listened at the receiver at Paris. After observing the effects for some time, he telegraphed by another line to Brantford, instructing Mr. Griffin, the manager, as to changing the arrangements of the coils. As a result of this, a combination was at last arrived at which resulted in loud and clear articulation being heard at Paris. He thought he could even recognize the voice of one of his speakers as that of his father. Surprised, because of his understanding that his father could not be on hand, he wired back to Brantford to ascertain if his father had actually spoken into the telephone, when the reply came that the voice was that of his father, who had been reciting into the telephone for some time. The first public demonstration was given within a few days of this event and conversation took place between Brantford and Tutela Heights.

"To Commemorate the Invention of the Telephone by Alexander Graham Bell, in Brantford in 1874."

MOHAWK INSTITUTE: INDIAN SCHOOL

BRANTFORD COLLEGIATE INSTITUTE AND TECHNICAL SCHOOL

So runs the inscription, cut in granite, ever enduring, on the Bell Memorial, unveiled in Brantford on October 24th, 1917, by His Excellency the Duke of Devonshire, Governor-General of Canada. Thus is commemorated the fact that in the city of Brantford, on Tutela Heights, was the telephone conceived; and that from this city emanated the first telephone message to be transmitted.

GRAND RIVER AND POWER DEVELOPMENT

The Grand River has often been a menace and expense in the matter of floods, but there is still a notable balance in favor of the stream in the matter of municipal service.

In the early days it constituted the motive power for many small flour mills, but the most important part which it played in the early portion of 1800 was in the use to which it was put by the Grand River Navigation Company. A large sum of money was invested in the construction of a canal to connect with the river to the east of the city and "slack water." Navigation was adopted which permitted of passage of boats of light draft to Buffalo. For a considerable period this canal was the only available avenue through which the produce of the country round about Brantford could reach an outside market, and produce for shipment was teamed to the place from a considerable radius. A tremendous impetus was thus given to the town. The encroachment of the railroads led to the final collapse of the navigation company, but it served a valuable purpose during the period of its existence, not alone for Brantford, but also in the development of the Grand River Valley.

That the stream could be still utilized in the matter of power developed, does not admit of any question. At the present time it is estimated that there is some 600 h.p. at the Slingsby Canal Head, and 1200 at the Locks, situated at the head of Grand River Canal. There is a great fall in the stream from Elora to Brantford, and by means of storage reservoirs—a plan successfully followed in the States and other countries—it would undoubtedly be possible to prevent the great water wastage during the spring freshets, and develop a large amount of continuous power for electric or other plants.

This is a matter which is well worthy of consideration and investigation.

TUTELA HEIGHTS, WHERE THE TELEPHONE WAS INVENTED

THE CARBONIZATION AND DISTILLATION OF PEAT

The value of peat lies in the direction of distillation rather than combustion, and on these lines it could supersede wood in the production of acetic acid, methylated spirit, ammonia and tar, the basis of so many dyes.

In the process of distillation, peat, being a light material, requires larger retorts than coal, and of a design which facilitates the transmission of heat from the surface towards the centre. Experiments have shown that revolving retorts produce the best results. The apparatus devised and described is on the principle of the roasting appliance used for coffee, chicory, etc., of course with the addition of a receiver for collecting the distilled vapor, the great object being to provide an apparatus complete in itself for continuous and all-round operation.

This apparatus consists of six cylindrical retorts, each mounted on its own axis and capable of uniform rotation,

THE BELL MEMORIAL HAS BEEN ERECTED TO COMMEMORATE THE INVENTION OF THE TELEPHONE IN THE "TELEPHONE CITY."

whilst the individual cylinders are arranged in radial relation to a rotary central pivot, so that the retorts charged with peat can be entered into and withdrawn from a stationary semi-circular furnace in succession.

When the apparatus is in operation there are always three retorts undergoing distillation in the furnace, the other three being outside, one condensing, another emptying, and the third recharging. The distillation takes on an average about 40 minutes for retorts holding a ton of peat, and making six revolutions per minute.

To enable the gas arising from the carbonized peat to pass out of the retorts, the hollow shaft of each is perforated so as to provide a passage from the inside of the retort to a collecting chamber in the axis of the pivot and thence to the stills for fractional distillation.

The rotary movement of the retorts ensures rapid transmission of heat from the furnace, and as this heat acts on a very large surface, the peat is uniformly carbonized in a short time at a relatively low temperature—a result which is impossible to obtain by any other process.

THE INSTITUTE FOR THE BLIND HAS ATTRACTIVE GROUNDS.

COAL STORAGE

For the prevention of heating in coal stacks, the following plan has been found to be of value in the South Wales coalfields in Great Britain. Wherever possible size the coal before stacking it, and put each size in a separate heap. Never stack heaps of "through" coal or mixed smalls to a greater height than 12 ft. If necessary, on account of lack of space, to store "through" coals or mixed smalls to a greater height than 13 ft., the stack should be laid in succeeding layers of not more than 3 to 4 ft. thick. These heaps should also be provided with perforated ventilation pipes, 3 in. to 4 in. in diameter. Iron or earthenware pipes should be used, one pipe to every 300 square feet of surface. The lower ends of these pipes should be at different heights from the ground throughout the stacks. A thermometer should be lowered occassionally through the pipes to ascertain the temperature at the various depths of the stack.

MAKING CORRECTIONS ON BLUEPRINTS

By Harrison Jenkins

Readers no doubt at some time or other have required to make some corrections on blueprints, and perhaps went through the laborious task of first blotting out the dimension in black with pen and ink before adding in the new figures. This scheme has two disadvantages: first the time necessary to blacken in the figures not desired, and second, that you cannot very well place the dimension in its former position, except you write the correction in white ink (which is not always easy to get). If white ink is not to be had, then it means that you must crowd in the figures somewhere else, not always a wise plan to follow.

An easy way to overcome all such trouble is to make little blocks of such length and width as best suits your usual needs. Four such blocks more than likely will cover all the changes you will ever desire. Glue (or hold by thumb tacks) pieces of blotting paper as shown.

Simply moisten these pads with the usual bleaching solutions of washing soda, caustic potash, or strong ammonia, in fact any alkali, and press the pad on your blueprint, when you will not only accomplish a quick job, but will make a neat white space in which you will be able to print in black ink your desired correction.

Mr. R. S. Wright, of Box 1,034, Sudbury, Ontario, writes: "I have always looked on POWER HOUSE as our own country engineers' journal, and it is up to us stationary engineers at this time to show our patriotism and support home industry."

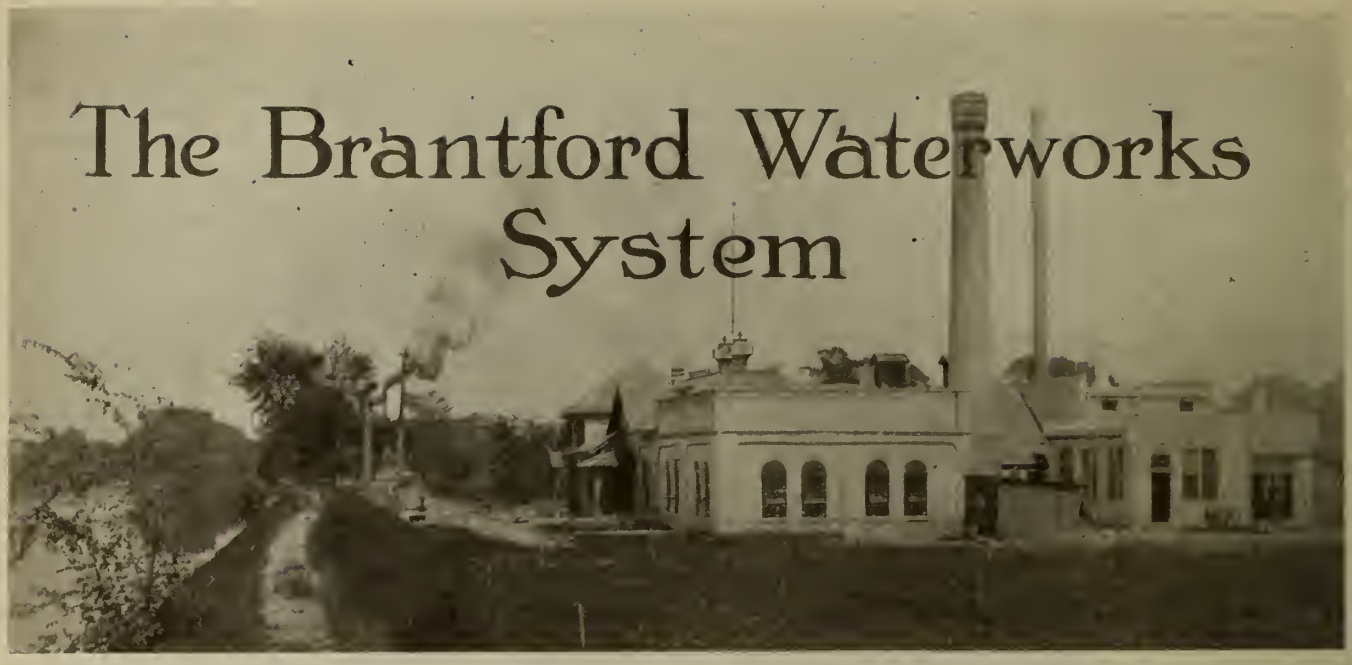
The Brantford Waterworks System



IN keeping with the importance the city of Brantford has as an industrial centre, the waterworks and other municipal utilities offer features of interest. The present waterworks system is the result of a somewhat rapid growth extending over a number of years, and the present layout in consequence combines in an efficient manner older equipment with more modern pumping units.

Historical

The waterworks system was established in 1870 by the Brantford Waterworks Company, a private corporation. The supply was obtained from a small spring creek, which had its source in the hills north of the city and empties into the Grand River. The pumping station was located on Colborne Street at the Clarence Street intersection. This first waterworks system was mainly used at the start for fire protection.

Owing to the unsatisfactory condition of the water, together with other features not satisfactory to the municipality, the company was taken over by the city in 1888 at a price of $64,700. which included about nine miles of mains.

The pumping station was moved in 1889 to its present location near the Grand River, and the Gaskell & Worthington pumps, mentioned further on, were installed. Nine miles of water main were also laid and a collecting gallery laid in the flats adjacent to the pump house.

Collecting Galleries

In looking for a suitable source of water-supply, a series of test wells were driven, and observations as to the depth and variations of the water level were made. It was found that over this district was a very porous soil, much of it a gravel bed, beneath which was a stratum of clay impervious to water. The average depth of soil overlaying the clay was about sixteen feet. The data collected showed that by laying a line of pipe on the surface of the clay a large quantity of water could be intercepted and collected for pumping.

The collecting gallery was constructed by laying tile pipe 15 in. in diameter in a trench excavated to the clay, the pipe being laid in two rows side by side, two

D. L. WEBSTER
Chief Engineer Brantford Waterworks.

feet from centre to centre. The pipes are perforated for about two thirds of their circumference and were covered with screened gravel to a depth of two feet before filling up the trench with the excavated gravel and earth.

The collecting gallery first constructed was laid in a south-westerly direction from the power station for a distance of 750 ft. The fall in this distance is about 4 ft. The bottom of the pump well is about 24 ft. below the station floor.

Underground water collected in this manner, when the watershed is such as to guarantee freedom from dangerous contamination, is an excellent means of procuring a public water supply. Observations made in Brantford would indicate that the supply is largely fed from the Grand River, the porous soil being a means of natural filtration.

As time went on the first collecting gallery became inadequate to supply the needs of the city, and in 1889 another gallery, this time of 24 in. tile, was laid. This gallery ran parallel to a hydraulic canal which supplies power to a number of factories, and about fifty feet from it to a point in the river flats. Part of the pipe is laid with closed joints and the remainder at the river flats with open joints.

The system proved inadequate, and the pipe line which runs to the river flats was extended into the river at a point opposite Dickie's Cove. This pipe was used to carry water to the gravel bed and an infiltration gallery was constructed 300 ft. long to take the water to the pumping station.

The system was extended in 1908. It was also found that the sediment from the river was choking the filter bed and a screen house was installed with stationary screens and a sedimentation basin. A 10 in. pump is also installed at the inlet at present and pumps the water into the pipe line supplying the natural filter bed. This pump is of the single stage type, and is driven by a 50 h. p. motor. Two intakes at present extend into the river, two being necessitated by the erratic behavior of the Grand River in flood time. Normally one intake should have about nine feet of water over it, but after a flood it is no unusual thing to find ten feet of gravel.

At the present time about 1,000,000 gallons of natural ground water are obtained, the rest being drawn from the

river and filtered through the natural gravel.

During the period of 1911-14, additional filtration galleries of a length of 6,000 ft. total have been added.

Pump Wells

All the water pumped is drawn from two pump wells. The older one, 15 ft. diameter and 20 ft. deep, supplies the steam pumps, and the latter one, 25 ft. diameter by 29 ft. deep, supplies the turbine driven and electric pumps.

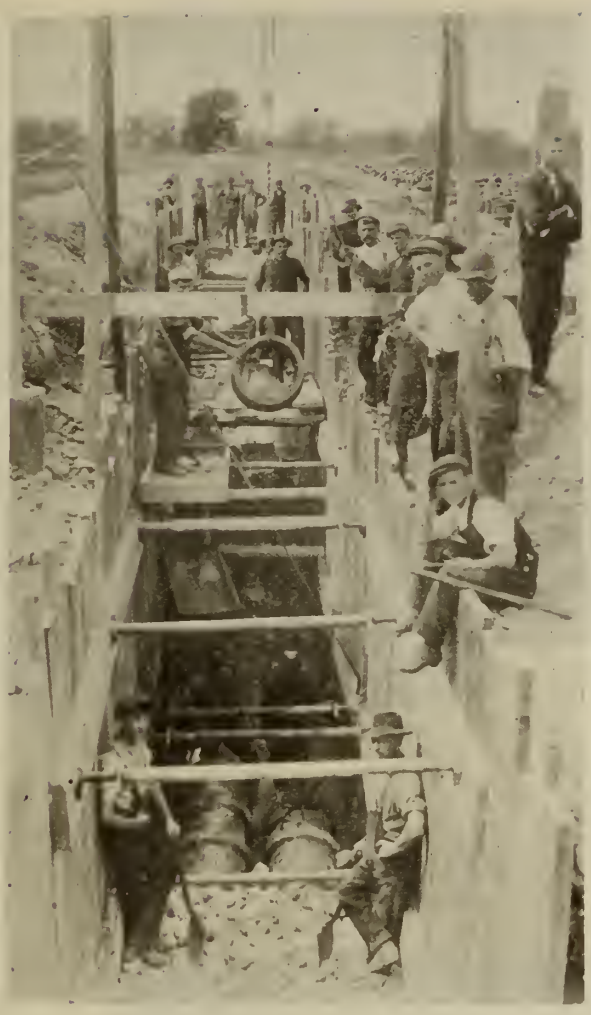
An emergency source of supply exists in the hydraulic canal adjacent to the station, and in this connection it may be stated, that all water from both the emergency supply and the filter beds is chlorinated.

Three artesian wells have also been sunk, but the water obtained was either salt or sulphur laden, and so not suitable for water supply.

Pumping Engines

Three pumping engines are installed. Two of these were purchased at the time of the reconstruction of the system in 1890. Each of these pumps has a capacity of 2,000,000 U. S. gallons of water per 24 hours. The Worthington pump has a high pressure cylinder of 14 in. diameter, low pressure 20 in. diameter, water cylinder of 1 4in. diameter, and has a 15 in. stroke. The pump may be run either condensing or non-condensing, and has been thoroughly overhauled this year, the major portion of the work being done in the waterworks machine shop.

The other two million gallon pump is of the Gaskill type, manufactured by the Holly Manufacturing Co., Lockport, N.Y. It is fitted with poppet steam valves and gridiron intermediate and exhaust valves. The steam cylinders, which are steam jacketed, are 12 and 24 inches in diameter, and have a stroke of 22 in. The water cylinders are 14 in. diameter. Jet condensers are fitted with four air pumps direct connected. Four feed pumps are also direct connected.



LAYING THE INFILTRATION GALLERIES. NOTE THE PERFORATED PIPES. THESE ARE COVERED WITH GRAVEL BEFORE THE BACK-FILL IS PLACED

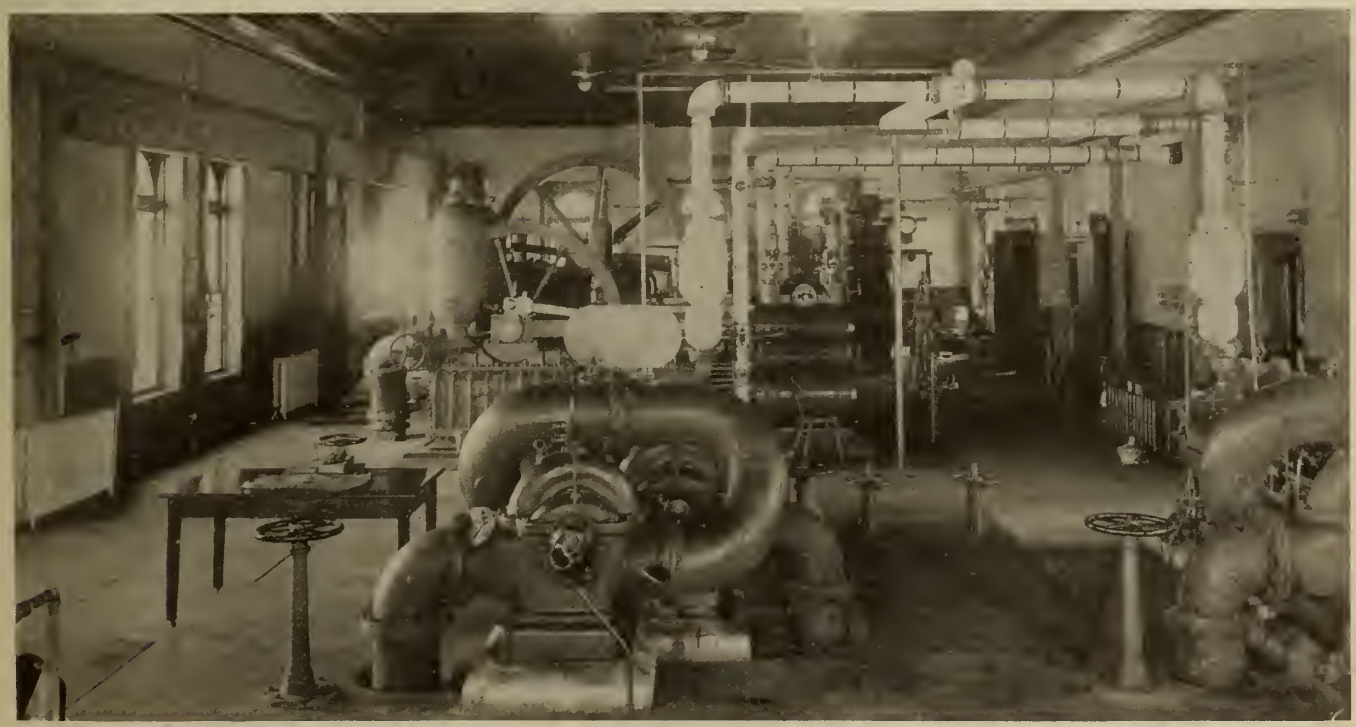
Six Million Gallon Unit

The third pump was purchased in 1900, and is No. 5 Holly, horizontal high duty twin compound engine with a capacity of 6,000,000 U.S. gallons per 24 hours. This pump was installed by the Waterous Engine Works, of Brantford. The high pressure cylinders are 18 in. diameter, the low pressure 36 in., and the water cylinders have 19 in. plungers. The stroke is 32 in. The valve gear is of the Corliss type, with positive cut-off regulated by water pressure.

This unit is fitted with two direct connected air pumps to feed pumps, and two jet condensers. This pump has been in almost continuous operation for fifteen years since its installation. The main rods are fitted with metallic packing.

Boiler Room

Three boilers were originally installed, sixty-three by 14 ft. These were later removed, and the present equipment consists of three John Inglis 72 by 16 horizontal return tubular boilers, and one 72 by 18 ft. Waterous boiler, the latter



GENERAL VIEW OF WATERWORKS.

SHOWING SWITCHBOARD AND DE LAVAL PUMP

being fitted with its own stack 6 ft. in diameter.

The above boilers are fed with feed water, heated with live steam in a Hoppes closed heater. A Cochrane 350 B.H.P. open feed water heater is also installed, and a Cochrane vee notch meter has been purchased for installation shortly.

The feed water is pumped by feed pumps, direct connected to the main pumping engines, and when these are not in operation by a Waterous duplex pump or a Davidson pump 12 by 6 by 11 in., made by the M. T. Davidson Co., New York City.

For an emergency source of supply, two injectors are fitted, a Morrison 1½ in. injector and a 1¼ in. Penberthy.

The feed piping is of brass throughout and is installed in duplicate. For checking purposes a two inch meter is used when required.

All the boiler settings are covered with Protecto-coat and the boilers are fitted with surface and circulating blow-offs.

The steam piping is being overhauled and duplicate mains put in.

McDonough damper regulators are fitted and a Canadian Westinghouse locomotive type air compressor is mounted on the wall of the boiler room. This latter is an exceedingly useful piece of equipment, as it does not only keep the pump air chamber filled with air, but is also used to run the Deane tube cleaner instead of steam. It also supplies the machine shop with compressed air for the operation of light tools.

Motor Driven Pumping Units

Hydro power makes an admirable source of power for the driving of waterworks pumping units, as the character of the load is well suited to the use of synchronous motors, and a material improvement in the power-factor on the transmission system results.

Two motor driven units are installed. The motors are of Canadian Westinghouse make and are of 250 h.p. each. They are of the synchronous type and take three-phase 25 cycle power from the Hydro-Electric System of Brantford, at 4,000 volts. The pumps are direct connected and run at 750 revolutions per minute. They are of De Laval make and are rated at 4,000,000 Imperial gallons each per 24 hours. By means of their three stage design, they are capable of delivering water at a head of 200 feet.

Each of these motor driven pumps can be run in series with the steam turbine driven pumps for fire purposes, and a total head of 300 feet obtained.

The two turbine driven pumps can also be coupled in series for domestic use, a head of 200 feet resulting in this case. Ordinarily the turbine driven pumps are used for fire purposes only.

Steam Turbine Units

Two De Laval steam turbine driven pumping units are installed, taking steam at 90 lbs. pressure. The turbines are of the single stage impulse type and run at 12,500 revolutions per minute. They develop 115 h. p. under normal rating, with a maximum of 145. They can be run condensing or non-condensing, and when run condensing, a vacuum of 28 ins. is obtained by means of a Wheeler surface condenser. This condenser is common to both turbines.

The water end of each of these units consists of two single stage pumps coupled in series with a resulting head of 100 ft.

A Bowser circulating and filtering system is being installed on the turbine driven units.

Switchboard

A slate switchboard of Westinghouse make controls the electrical equipment of the plant. The first panel is the incoming line panel with oil breaker, graphic voltmeter, and voltmeter and ammeter plugs for the indicating instruments on a swinging bracket. The oil circuit breaker is fitted with a no voltage release.

The next panel meters the plant load and is fitted with a graphic power factor meter, graphic wattmeter and an integrating wattmeter.

Panel No. 3 controls the booster station and screen house described below, and is fitted with two knife switches for the remote control of the motors in the booster station. Ammeter plugs and a breaker are also supplied. For the re-recording of the pressure developed at

SHOWING THE DE LAVAL TURBINE DRIVEN AND MOTOR DRIVEN PUMPS

BOILER ROOM.

the booster station a Bristol long distance recording pressure gauge is mounted on this panel.

Panel number four controls the lighting, two supply circuits are provided for by a double throw switch, one the Hydro-Electric fed from station transformers and the other a sixty cycle supply obtained from a power plant run by means of the Grand River.

Panels five and six control the synchronous motors, and are fitted with indicating power factor meters a. c. and d. c. ammeters, the latter for the exciter and the usual field rheostats, etc. First, second and main breaker switches are installed for the starting and running positions of the synchronous motors.

The motors are started by means of an auto-starter which may be used with either machine.

Garton-Daniels lightning arresters are used.

Discharge Mains and Metering

The city of Brantford is fed by three discharge mains from the pump house. These mains are 10 in., 14 in. and 20 in. in size, and a fourth main of 8 in. pipe feeds West Brantford. The mains are all so arranged that any group can feed into any main independent of the others. Large relief valves are installed on all mains at the pump house.

The plant discharge is all metered by two Venturi meters. An eighteen inch Venturi meter takes care of the discharge of the steam turbine and motor driven centrifugal pumps, while a similar meter of 20 in. throat meters the discharge of the older steam pumps.

Chlorinating Apparatus

All the water is chlorinated with liquid chlorine apparatus, two units being installed by the Electro-Bleaching Gas Co., New York City.

These units automatically feed the chlorine gas in a measured amount, depending on the flow of water through the Venturi meter tubes.

Heating System and Drips

A Burnham receiver pump collects all jacket returns from the steam pumps, and all drips around the plant, returning the hot water to the boilers.

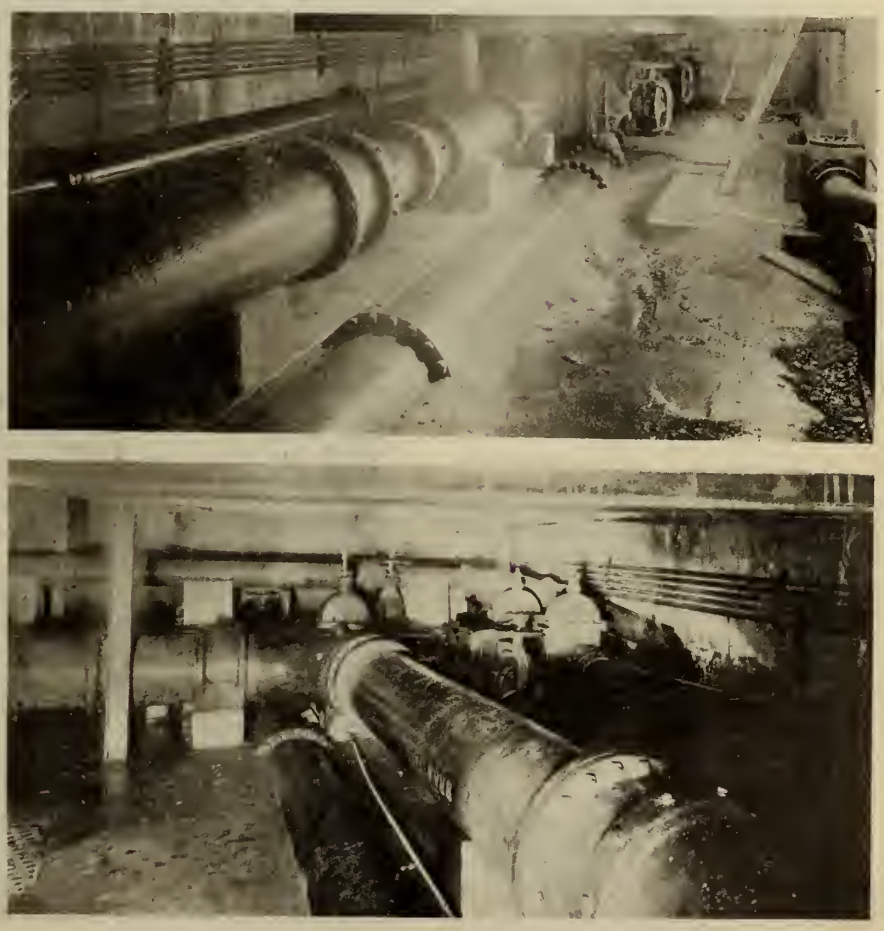
The exhausts from feed and vacuum pumps during the winter months are used for plant heating, the live steam heater being used for feed water, while in the summer months the Cochrane open feed water is used. The Webster system of steam heating is used by Darling Bros., Montreal.

Machine Shops

In any waterworks system much repair work always has to be done to hydrants, water meters, etc., and to station apparatus. A machine shop then, while not an absolute necessity, is an extremely useful part of the plant equipment, and one which in the course of a year saves considerable money and time.

All wattmeters are repaired and tested, all valves and fire hydrants are repaired, together with repairs to any of the engines or turbines forming part of the pumping equipment. The steam pumps have been completely overhauled and all work done on them except some which was too big for the lathes has been done in the machine shop.

A Hendey toolroom lathe, 14 in. by 6 ft., forms part of the equipment, together with a Lodge & Shipley 20 by 10 ft. lathe. Other equipment includes a 16 in. shaper and a 20 in. drill. All

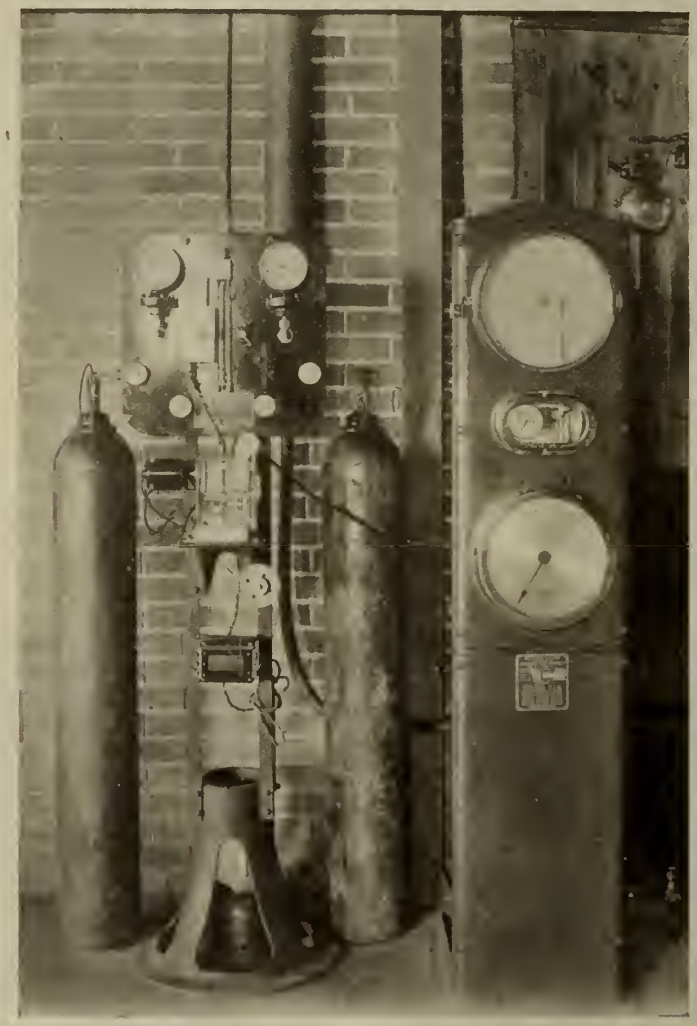


ARRANGEMENT OF PIPES AND VENTURI TUBE IN PIPE TUNNEL

drills and small tools are kept in lockers adjacent to the tools on which they are used.

The floor is part concrete and part wood surfaced. The concrete floor is useful for the repair of the waterworks motor trucks and traction engine. The remainder of the floor is built up of a concrete sub-floor, on top of which is laid a 3 in. plank floor and a lighter plank floor.

Fire hydrants are tested in a concrete lined pit provided with mains and



VENTURI METER AND CHLORINATING APPARATUS.

feet for their ready attachment and removal.

A ten ton Herbert Morris crane is provided in the engine room for plant purposes.

Distribution System

At the end of 1918 the distribution system had a total length of 63 miles, 3,434 feet, made up as follows:

20	in. mains	6,818 ft.
14	in. mains	16,997 ft.
12	in. mains	4,082 ft.
10	in. mains	8,488 ft.
8	in. mains	34,694 ft.
6	in. mains	160,451 ft.
4	in. mains	104,544 ft.

338 fire hydrants and 478 valves are installed on the systems. Service connections to the number of 7,050 have been made and 2,123 of these are metered.

Booster Station

A portion of the city of Brantford is at a considerably higher level than the remainder and for the better serving of this part of the city, a booster station has recently been put into service.

This station contains two centrifugal pumps of De Laval make, rated at 300 imperial gallons per minute each. These are driven by two Canadian Westinghouse 550 volt, three phase, 25 cycle induction motors of 20 h. p. at 1450 revolutions per minute. The pumps serve to raise the head of the water supply by 100 ft. The motors are provided with oil circuit breakers provided with plain overload release in series, with starting contactors controlled from the main pumping station. Two control wires and three wires for the Bristol long distance pressure gauge are carried on an overhead pole line to the main pumping station, and the station is thus operated without the employment of attendants

Pumpage

The pumpage varies between wide limits, a variation of between 1,000,000 and 8½ million gallons per 24 hours being observed between the winter and summer months.

Personnel

The waterworks is managed by F. W. Frank, manager under the board of commissioners. The waterworks staff is composed of D. L. Webster, chief engineer; Geo. Drury, resident engineer, and the operating staff. The staff are on eight hour shifts, one fireman and an engineer being on duty during each shift. The cleaning out of the galleries requires the services of an additional man from time to time. Five men are employed in the repair shops and on the repair gang.

ANNOUNCEMENT

Wm. B. Scaiffe & Sons Company, of Pittsburgh, announces the opening on July 1st of a Chicago sales and engineering office at 38 South Dearborn Street, with Charles F. O'Hagan, formerly chief engineer of the company at Pittsburgh, as resident engineer and manager.

This company is the oldest manufacturing concern west of the Allegheny Mountains. During the more than one hundred years since their business was founded they have from time to time as conditions arose added to their manufacturing facilities. They now manufacture black or galvanized, riveted, brazed or welded steel tanks for air, gas and liquids, steel shipping drums, range boilers, steel structures, also the well-known We-Fu-Go and Scaiffe water softeners and filtering equipment.

The Betson Plastic Fire Brick Co., Inc., was organized on May 17, 1919, and Frank J. Jewell was elected president and secretary and Nelson Adams, vice-president and treasurer, thereof. This corporation has been organized for the purpose of selling and marketing Betson Plastic Fire Brick and Betson Hi-Heat Cement.

SPECIFICATIONS FOR BOILER FEED REGULATION

An eight-page bulletin, embodying specifications for the Copes system of boiler feed regulation has just been published by the Northern Equipment Co., Erie, Pa. Size 8½ x 11—convenient for filing. A cover is provided with punched holes for adding future bulletins or specifications that will be published by the company.

The bulletin discusses the following points: principle of operation; heat storage; reduction of furnace temperature fluctuations and sudden load change; service performance; constant characteristic; thermostat; control valve; standard dimensions and drilling, and the Copes Steam Pump Governor. The last page is devoted to a review of the company, the history of boiler feed regulation and the service rendered by the manufacturers.

Boiler Room of the Sheet Metal Products Co., Ltd.

A Power Plant Generating Steam for Factory Use and for Power Generation Which is Operated at a High State of Efficiency—Good Operating Results Have Been Obtained From the Apparatus Installed

By W. F. SUTHERLAND

THE isolated plant, when economically operated, is well able to compete with central station energy where steam is required for plant processes or for heating. This fact is well illustrated in the power plant of the Sheet Metal Products, Ltd., Toronto, where tests have been made at various times by central station engineers to determine the feasibility of purchasing power from outside sources.

The accompanying article is descriptive only of the boiler-room, the engine-room and its equipment being overhauled at the present time and an additional engine-driven unit installed. It is hoped at a later date to give a further description of the whole plant and to present some figures giving operating economics, etc.

Boiler Room

Three Erie City boilers are installed. These boilers are of the vertical water tube type and are rated at 316 b.h.p. each. They were made by the John Inglis Co. and were installed in April, 1916, the fires being started on August 2 of the same year. Each boiler has a total of 3,160 sq. ft. heating surface, and the boilers are fitted with McDonough feed-water and damper regulators. A pressure of 140 lbs. gauge is carried.

Two of the boilers are arranged in a double setting, the third one being isolated. Detroit stokers are installed on all three boilers and the accompanying illustrations give a good idea of the general arrangement of the plant, together with the constructional features of the boiler settings and stoker design. Fig. 1 shows the stokers in the foreground with the overhead track and coal car for coal handling. The coal is lifted from the covered storage pile outside by means of a bucket conveyor and discharged into the bunker at the top left hand corner of the illustration; from this it is fed into the bottom dump car, seen over the far stoker. The steam header is also visible in this illustration, and the Lunkenheimer automatic non-return stop valves on each boiler are also clearly seen.

FIG. 1—GENERAL VIEW OF BOILER ROOM SHOWING STOKER, HOPPERS, ETC.

Fig. 2 shows two of the three stokers with the driving mechanism and control. Ashes and any crushed clinker fall into the pits below, from whence they are removed as required. Natural draft is used and draft gauges are provided.

Fig. 3 shows an interior view of one of the stokers. At the time the picture was taken ashes were present on the right hand side of the inclined grates and on the clinker crusher at the bottom. One of the most interesting features of this installation is the excellent condition in which the firebrick furnace linings and boiler baffling are found. During the whole time, three years, in which the plant has been operating, only one brick has had to be replaced, and that a tuyre brick over the grates on the left hand side of the illustration. The firebrick, of Savage make, are as good to-day as when they were originally installed.

Fig. 4 shows a view taken in the combustion chamber in the opposite direction to that shown in Fig. 3. This view shows the boiler tubes, the firebrick lining and the boiler baffling, visible between two tubes in the centre of the illustration. The excellent condition of the baffling and brickwork is clearly visible.

The boiler settings are provided with Diamond soot blowers, blown-down columns, and are covered with Statite plastic boiler covering.

The excellent condition in which the boilers are maintained is largely due to the monthly cleaning down which they undergo and to the thorough overhauling which is given them at the time of their inspection once a year.

Very little scale is formed in the boil-

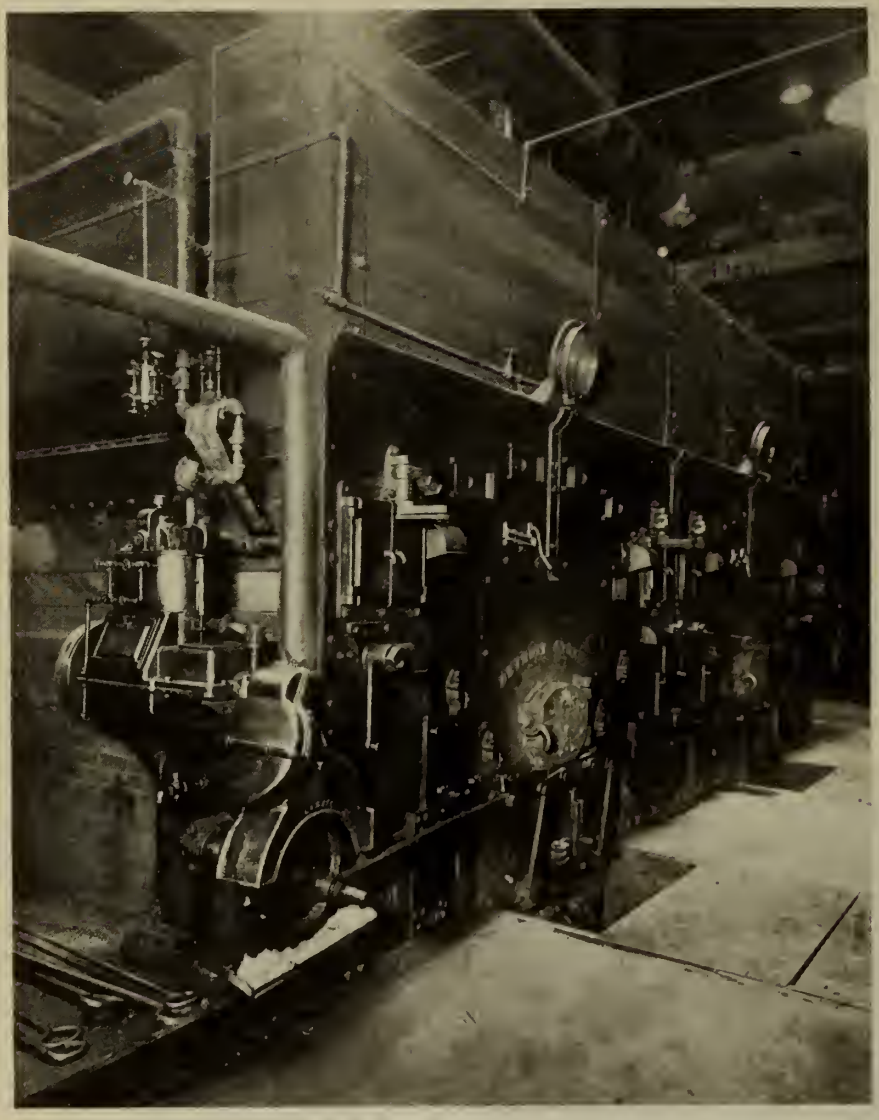


FIG. 2—PARTIAL VIEW OF DETROIT STOKER INSTALLATION.

ers, about one-sixteenth being the greatest amount ever found. No tube cleaners are needed for its removal, as it comes away easily. The feedwater in large measure accounts for this freedom from scale, as it almost entirely consists of condensate from the exhaust lines, together with a little make-up water.

The boilers, when the engine-room is again in operation, will feed two 400 h.p. cross compound engines of McIntosh and Seymour make, and one 100 h.p. vertical high speed engine made by Reavel, Ipswich, England. This latter drives a direct connected d.c. generator for plant lighting, etc. The two larger units are also direct connected to d.c. generators supplying the factory power requirements.

In addition to feeding the engines the boilers also supply steam to the enamelling room furnaces, a 2½ in. line being run. A 3 in. line is also run to the remainder of the factory and supplies whatever steam is needed for general purposes.

Exhaust steam is used for kilns, driers and the usual shop heating requirements. All exhaust from the engines is taken through an oil separator of special design, and from this enters an exhaust manifold from which all lines are piped. Live steam is used when the engines are shut down, and for this purpose a live steam connection is made to the exhaust manifold through a Keely reducing valve, balanced up to one lb.

All condensation from the exhaust lines, heating mains, plant returns, etc., is taken to one central point in the boiler-room. Each separate line is fitted with a two-way header, provided with valves and discharging into either one of two manifolds. One of these manifolds delivers condensate to a Blake and Knowles vacuum pump, which discharges into the Hoppes feed-water heater. The other manifold discharges directly into the heater. Both of these manifolds are provided with valves, and it is thus possible to operate the return system as a gravity return system or a vacuum system.

Bawden and Goldie and McCulloch Co. outside packed plunger type feed pumps are provided and are equipped with Richardson-Phoenix lubricators.

Between the feed pumps and the feedwater heater a hot water reservoir or tank is installed for the evening up of any fluctuations in the return of condensate. This reservoir is fitted with a by-pass, so that it may be cut out at any time for cleaning or inspection.

All steam piping, both exhaust and live steam, is lagged with insulation provided by the Armstrong Cork and Insulation Co.

Remember our remarkable offer of one dollar per year for POWER HOUSE. Now is your opportunity to secure this paper for any number of years at that rate. Apprentices especially should take advantage of this offer.

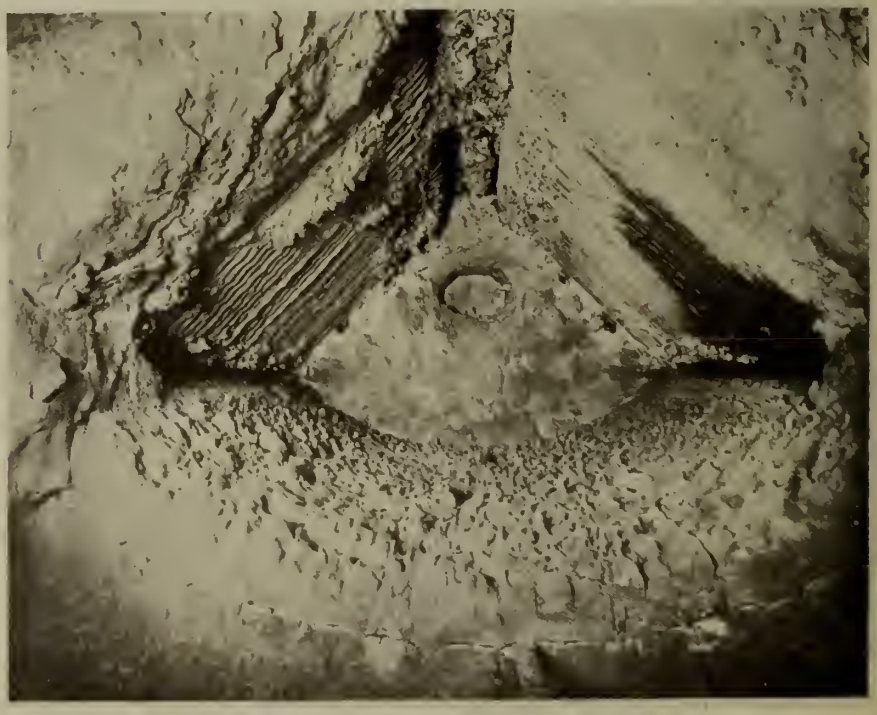

FIG. 3—INTERIOR VIEW OF FURNACE LOOKING TOWARD STOKER. THE BRICKWORK HAS BEEN IN USE FOR THREE YEARS.

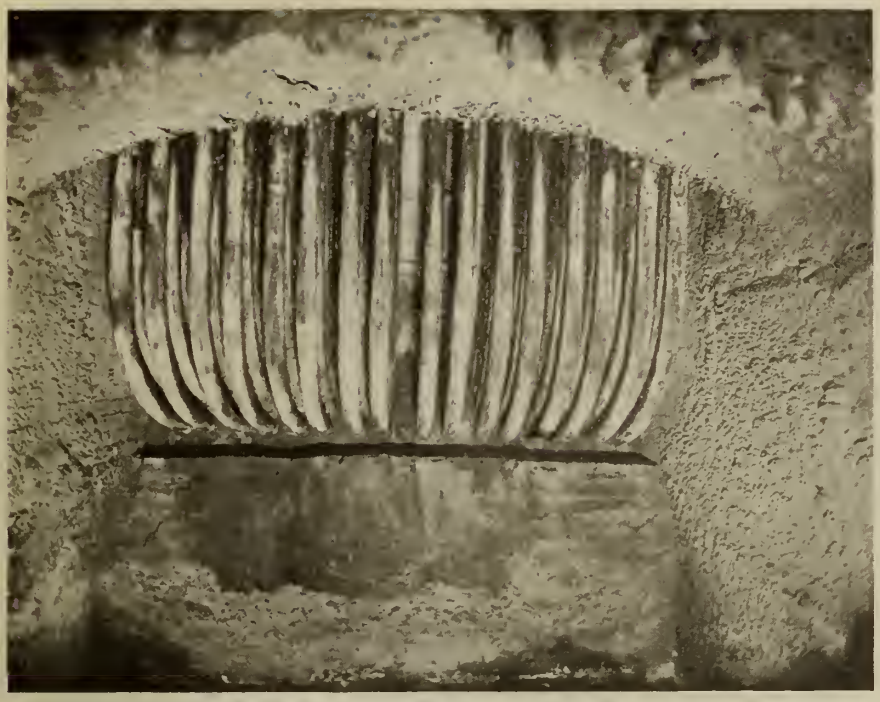

FIG. 4—INTERIOR OF COMBUSTION CHAMBER. NOTE THE EXCELLENT CONDITION OF THE BAFFLING AND BRICKWORK.

GASIFYING COAL COMPLETELY

In view of the atmosphere of controversy which at present surrounds the problem of carbonization, and particularly the future methods to be employed, it is interesting to refer to endeavors which are being made in the direction of the complete gasification of coal and coke in one operation. It is generally known that if a ton of coal is treated in special plant for the purpose it may, apart from the ash it contains, be converted entirely into gas, of which product it will yield some 65,000 cu. ft., saving a calorific power of about 375 B.Th.U. The "Double-Gas" plant for this purpose is the invention of an Englishman, and particulars are now to hand of a plant which is being employed for the same purpose in Germany, and which is made by the well-known Dellwik Water-Gas Company of Frankfort.

The plant possesses some novel features, but consists in the main of a producer, the lower portion of which is divided into two halves by a certain wall. Coal is fed into the upper portion and is converted into coke before reaching the divided chamber. The process is very similar to that employed with the ordinary type of water gas plant, in that air and gas are admitted during intermittent periods; but in this case a superheated supply of air is utilized, and by this means the fuel in the coke chambers is raised to a temperature of 1,400 deg. C., the producer gas being taken off at a point which corresponds with the zone where the coal is completely changed into coke. During the gas making period a gas outlet is opened above the coal bed, superheated steam is admitted to the base of the producer, and the water gas thus produced rises through the coke and passes upwards through the entire column of coal. This water gas at the time of its formation is at a temperature of some 1,300 deg. C., and provides the greater part of the heat for the carbonization of the coal, the gases from which are swept from the producer and carried through subsequent plant of the ordinary type for the removal of sulphuretted hydrogen, tar, and ammonia. Condensation is largely effected in the upper layers of the coal bed so that the gas leaves the producer outlet at a temperature of only some 200 deg. C. The producer gas yielded during the blowing period is not wasted, but is utilized for superheating the steam for gas-making.

The duration of the intermittent periods of blowing and gas-making varies in accordance with the class of coal employed, but generally speaking the "blow" continues for from one to three minutes, while gas-making may be carried on for from five to ten minutes, and it is found that by employing an excess of steam a maximum of ammonia is obtained. An unsatisfactory feature of the process, a feature which is absent from the English system, is the necessity for admitting a certain quantity of air during gas-making. It is said that the quantity of heat demanded for the coking of coal is greater than that which can be supplied from the stream of water gas, and hence the necessity for introducing air; but it seems that by modifications in the working it is possible to produce a gas of moderately high calorific power or one of lower quality. When a comparatively good coal is employed the final mixture of gases obtained contains 50 per cent. of hydrogen, 10 per cent. of methane, 30 per cent. of carbon monoxide, and 1 per cent. of unsaturated hydrocarbons. The calculated calorific power of such gas is 384 B.Th.U. per cu. ft. and in this respect it corresponds very closely with the suggestions recently put forward for the provision of a low grade gas by Mr. George Helps, of Nuneaton.

Mr. R. E. Wright, of the R.D.V. Lodge, C.A.S.E., of Drumheller, Alberta, writes: "We will do our best to make this district 100 per cent. strong with POWER HOUSE and help to maintain and advance the magazine, which we all feel is second to none in America."

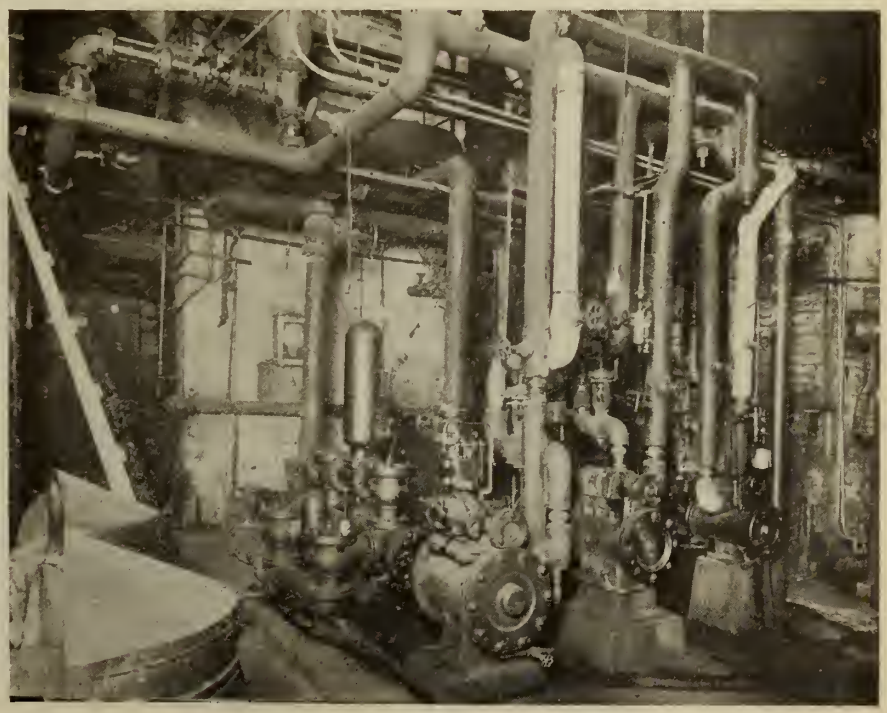

FIG. 5—FEED AND CONDENSATE PUMPS. THE FEEDWATER HEATER WILL BE NOTICED TO THE REAR ABOVE THE PUMPS.

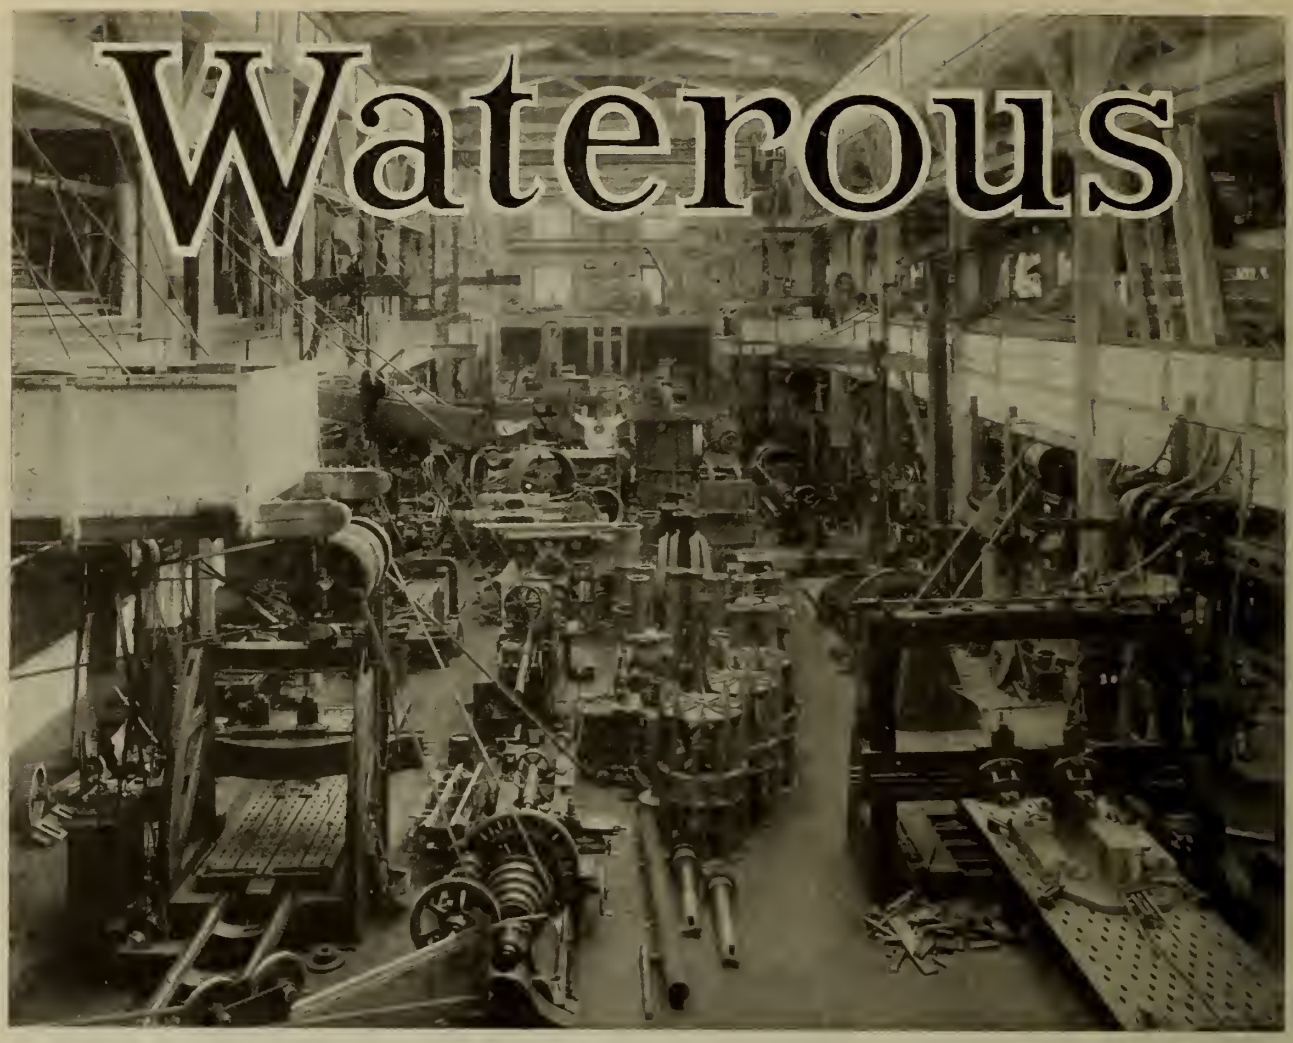
Waterous



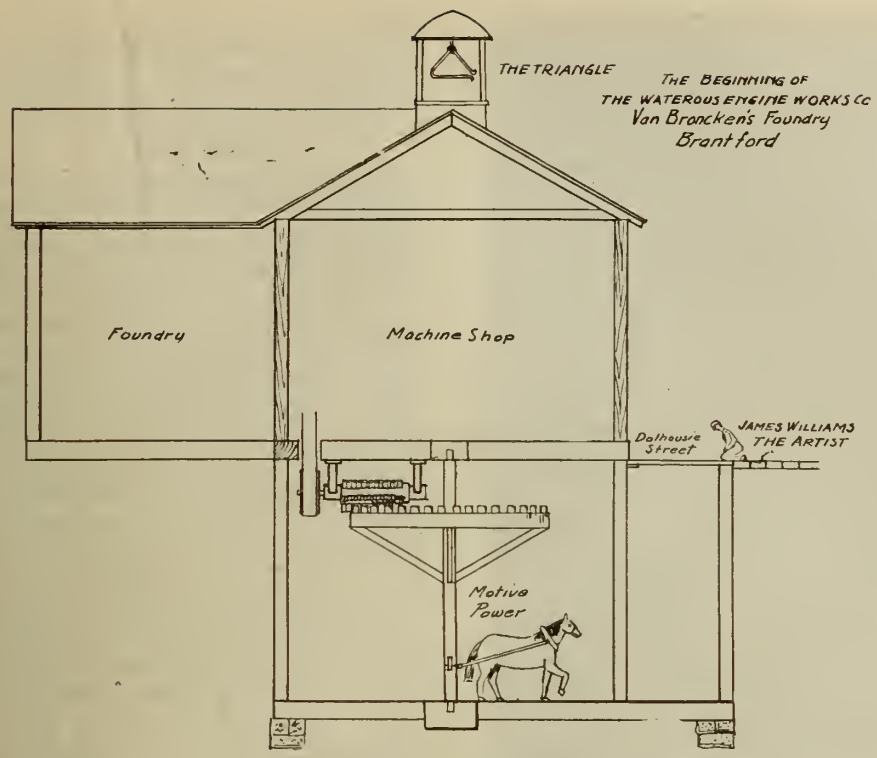
THE Waterous Engine Works Company, of Brantford, Ont., enjoys the reputation of being one of the oldest industrial firms in Canada. Seventy-five years is more than the span of man's life, and while the founders of the original business have long since left the sphere of their earthly activities the business which they established remains a monument to the business ability and integrity of both the founders and their present successors.

The busines was started in 1844 by P. C. Von Brocklin, under the name of P. C. Van Brocklin & Co. The scene of operations was a small building on Dalhousie Street, present-day inhabitants knowing of it in the form of a livery establishment. Conditions under which the plant was operated seem primitive in the light of modern conditions, yet the very source of power by which the work was then done is to-day a source of much interest and pride to the management. In 1848, when the late Charles H. Waterous became interested in the business, the motive power for driving the machinery in the little engine shop amounted to one horsepower nominal, brake and indicated, and was developed by a single specimen of man's best friend, which, with traditional faithfulness, journeyed round the cellar floor from morning till night. One of our illustrations shows the means whereby Dobbin carried on his share of the foundry's early operation. The artist from whose sketch the engraving has been made, drew it from memory, and has represented himself as looking through a grating on street level at the equine motive power.

A LARGE FLY WHEEL ON THE BORING MILL.

In 1854 the business was reorganized under the name of C. H. Waterous & Co., and in 1874 it was incorporated under Dominion Charter under the name of Waterous Engine Works Co., Ltd.

From its inception the business was successful and prospering, and grew, requiring from time to time successive additions. In the early days the industry devoted its attention to the production of miscellaneous articles castings, stoves, boilers, and general work.



THE ORIGINAL MOTIVE POWER USED

These lines were in time replaced by agricultural engines and general boiler work, power plant equipment, sawmill machinery, pulpmill machinery, fire apparatus and road-making machinery.

The power plant equipment manufactured by this firm includes high-speed engines, heavy duty mill engines, portable and stationary engines, boilers of all types, return, tubular, vertical, locomotive, and marine. Accessories such as pumps, injectors, air compressors, condensors and coal handling plant are also made.

The production of sawmill equipment has advanced in keeping with the development of Canadian forest wealth. From the time the timber logs are drawn from the river down which they have been floated from the lumber camp until they leave the sawmill in the form of rough-dressed lumber, the material is seldom out of touch with some item of equipment of Waterous manufacture. Log handling apparatus, feed carriages, large and small sawmills, band mills, etc., may be mentioned as giving some idea of the scope of this item of manufacture.

The great growth of the paper industry in recent years afforded an allied field in which the company's experience stood it in good stead. Complete pulping machinery, barkers, grinders, beating engines, screens, disintegrators and accessory equipment indicate the scope for mechanical equipment offered in this industry.

With the coming of the automobile, good roads have become a necessity, and Waterous products have more than kept pace with the requirements of the good roads movement. Starting with the rough rock and passing over crushers, screens, conveying apparatus and graders, the culmination of roadmaking plant is reached in the steam road roller.

The adoption of motor fire apparatus by city fire departments created a considerable demand for equipment of this type. Steam fire engines, self-propelled apparatus, and horse drawn sets with gasoline pumps, are some of the products of this department, together with hose waggons, reels and hook and ladder trucks.

Modern Plant Development

In 1895 it was found necessary to erect an entirely new plant on a new site as the old plant in the centre of the city of Brantford had outgrown the business and there was no further room for extension. The new site, consisting of nearly thirty acres of land, was secured within the city limits, and upon this was erected a number of modern buildings, suited to the class of work that the company was turning out.

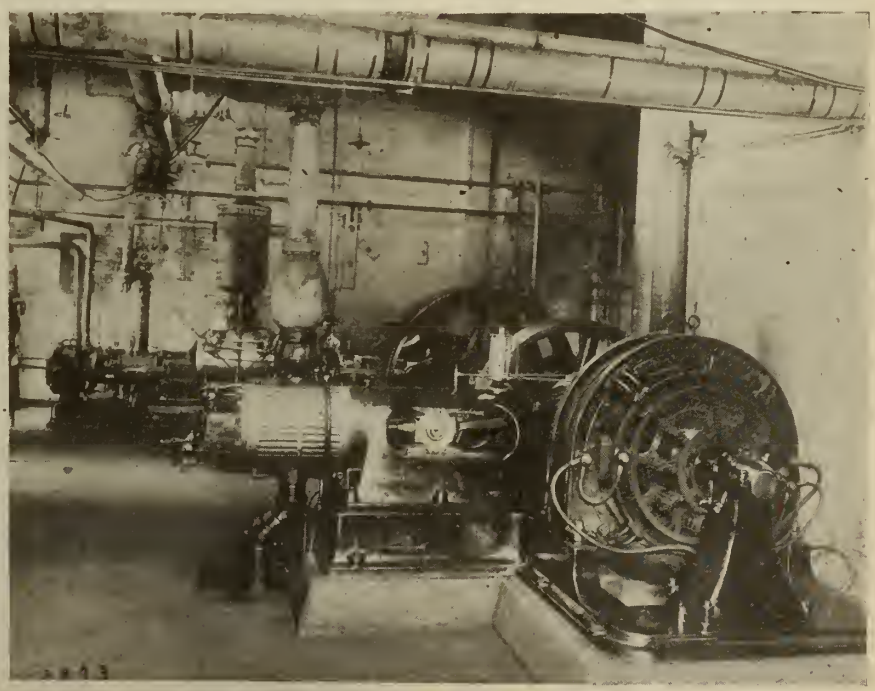
Since 1895 a very large growth has taken place in the business, and very considerable extensions and additions have been made to the original plant as laid down.

In 1912 a new foundry was built—this is a thoroughly up-to-date all steel building of very heavy construction. It is 243 ft. long by 114 ft. wide. It has one centre bay of 50 ft. span and two side bays. The centre and one side bay are served with overhead cranes. The other side bay has above it a reinforced concrete gallery, upon which is stored all the various sands used and the sand-mixing apparatus. Also upon this is located the charging floor for the cupolas and also the brass castings department.

Below the gallery is located the core making department, consisting of three large up-to-date core ovens and all modern core making equipment. The capacity of this foundry, in heavy and light castings, is in the neighborhood of 30 to 35 tons per day.

Outside of the foundry the steel work of the centre bay is extended for 150 ft. This is arranged so that the main crane can run out on this crane way, and under it is stored flasks and other equipment used in the production of the castings.

The main machine and erecting departments occupy a building 300 ft. long by 120 ft. wide, made up of one centre bay with overhead traveling crane and two side bays with galleries above. The heavy erecting and machine work is done under the centre bay. Lighter machine work and erecting is done under the side



WATEROUS ENGINE WORKS; ENGINE ROOM

BOILER ROOM, WATEROUS ENGINE WORKS

bays and on the side galleries. One gallery is devoted to a pattern and millwrighting department.

In addition to this shop there is also another machine shop for small machine work. This is 180 ft. long by 8 ft. wide.

As the lines manufactured by this company are very extensive the patterns required for the production of castings are numerous and a very large three-storey pattern storage department is provided. This building is 42 ft. wide by 209 ft. long.

The plant is equipped with its own smithy department, which is located in a building 100 ft. long by 50 ft. wide. This building is equipped with heavy steam hammers, bulldozers, hand forges, and all other necessary appliances for the production of a large variety of heavy and light forgings.

The boiler department is located in a building 300 ft. long by 79 ft. wide. This building has one large overhead crane and one side bay. The side bay being devoted to machine work and light sheet iron and boiler work, the centre bay being reserved for heavy machine work and for the erecting of all boilers. The equipment in this shop is of the very latest, consisting of two hydraulic riveters, one of 50-ton capacity and one of 150-ton capacity, both served with overhead cranes. Heavy and light bending rolls, heavy sectional hydraulic flanging press, and all necessary equipment for the turning out of sheet iron work, light and heavy stationary boilers and light and heavy marine boilers. The main bay crane way is extended some 200 ft. outside of the building. Under this is stored plate and other material supplies used in the boiler shop, and the shop is so arranged that the main crane may be run out on this runway for the purpose of picking up such material as may be required from time to time.

Power Plant

Making boilers, engines and other power plant equipment, this firm might naturally be expected to develop its own energy whether mechanical or electrical. The boiler room contains a battery of six Waterous return tubular boilers, three of them being 78 by 16 ft., and the remainder 72 in. by 16 ft. These give a total of 800 boiler horsepower and carry a steam pressure of 115 pounds. The feed water is heated by a 1,000 h.p. Webster open feed-water heater.

The main shop drive is by belt from a Rigeway type Corliss engine manufactured by the Waterous Company, and having an indicated horsepower of 250 at 235 revs. per min. This engine has a cylinder of 19 in. dia. by 18 in. stroke. A high-speed McEwen 16 by 16 in. engine, also of Waterous make, is installed, and develops 210 horsepower, driving a Ridgeway direct current generator of 125 kw., 225 v. rating.

Hydraulic power is obtained from a duplex steam-driven plunger pump and pneumatic power from two air compressors, one Blaisdell 18 by 12 by 12, and one Franklin 18 by 14 by 14.

Steam Engine Products

The varied requirements and frequently strenuous conditions under which prime movers are operated in the pioneer districts of Canada, are in some measure responsible for the different types of engines built by this company.

Steam engines are built suitable for the rough usage of the lumber camp and on the other hand the highest type of engine for electric generator connection, factory and mill driving, where economy and regularity of operation are the chief desiderata, is found in products of the Waterous Company.

The former type is exemplified in the

SCOTCH MARINE BOILERS IN THE BOILER SHOP

centre crank engine of general and heavy duty types in which power, durability and simplicity are outstanding features. This design is characterized by the use of a Corliss type of steam valve located under the cylinder and operated by a single eccentric on the crank shaft. A perfectly balanced valve is obtained, which, along with the short travel and large bearing surfaces insures a high degree of reliability and long life.

McEwen Engines

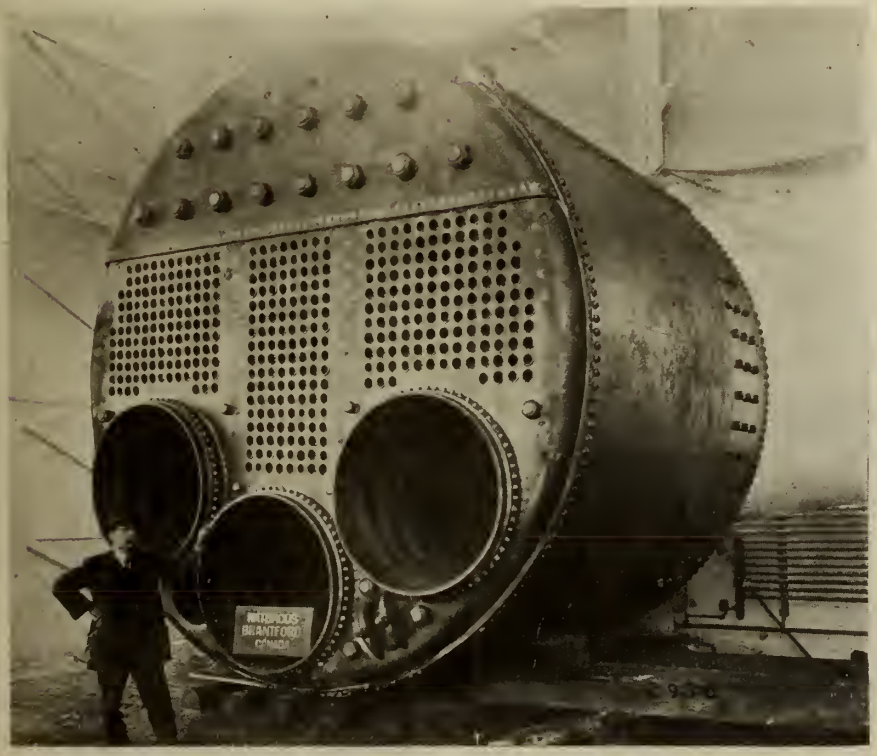
More than twenty years ago the McEwen engine was placed on the market by the Waterous Co., and an enviable record has been built up around this type of prime mover. It is a high-speed automatic engine specially designed for close governing under excessive load fluctuations, such as electric service of all descriptions, mine haulage, crane work, etc. The engine bed is of heavy construction, with the sides open for the purpose of adjusting cross-head shoes and wrist pin boxes. Guides, main bearings and end of bed are machined at one setting to insure accuracy. A feature of the main bearing design is the arrangement of the babbitt liners, which may be removed by simply relieving them of the weight of the shaft, thus obviating the necessity of removing armatures of direct connected units before removing bearing liners.

A swivelling eccentric adjustment is provided for the cross-head shoes, which assures a full bearing on the guides and allows adjustment to be made by simply loosening a single nut and turning a bolt to draw in or force out the shoe as required. Accurately balanced discs are fitted to the crank shaft, which is a single-piece forging.

The remarkable regulation for which these engines are noted is obtained through a simple form of quick-acting governor of the flywheel inertia bar type. Governing limits of one revolution are obtained, the instantaneous variation in speed when full load is thrown on or off being seldom more than 1 per cent.

EXCELLENT TRANSPORTATION FACILITIES ARE PROVIDED.

In the building up of an industry connected at their source with so many lines of industry, experience is necessary, and this is reflected in the personnel of the company. When C. H. Waterous died a few years ago the responsibility of the work rested upon his son, C. H. Jr., who, along with the other members of the firm directs the activities of the company, the officers being: President and general manager, C. H. Waterous; assistant general manager, C. A. Waterous; secretary, D. J. Waterous; sales manager and director, L. M. Waterous; treasurer, W. T. Mair.



MARINE BOILER FOR SEA GOING TUGS FOR THE AMERICAN GOVERNMENT.

PRESERVATION OF WOOD

Seven years' experience has proved zinc fluoride as a preservative of wooden poles. It compares favorably with copper sulphate. When complete impregnation of the wood is unnecessary, a partial application of sodium fluoride will be found to exhibit great preservative action.

INTERNAL COMBUSTION ENGINES

The great superiority of the Diesel engine is almost wholly obtained by the high compression which it is possible to give to the air before admission and ignition of the fuel oil to the cylinders. Compression is the chief characteristic of the internal combustion engine and is the essential foundation of all heat engine cycles. The Carnet cycle is the ideal one owing to its perfect efficiency, but cannot be strictly adhered to in practice, since the engine becomes too bulky and heavy even for small powers. The weight of an engine of this type when working under the maximum pressure obtaining in the modern Diesel at about 17 tons per brake horse-power, whereas the modern engine only weighs at least one-hundredth of this figure. The original Diesel engine was intended to work on the ideal cycle, although somewhat different from the ideal is still the nearest approach to it and hence its high state of perfection.

Hydraulic Plant of Watson's Limited

A Hydraulic Plant at Brantford, Ont., Which Utilizes Water From the Grand River for the Supplying of Power to a Textile Mill—Water Softening Plant Also a Feature of This Installation

MANY of the rivers of Western Ontario furnish sufficient water power to supply at least some of the requirements of the manufacturing industries in the nearby towns and cities. The Grand River is an excellent example of this fact, for while the head obtainable at any one point is nowhere very great and while its flow is subject to wide seasonal fluctuations, considerable power is developed along its course.

The Watson Mfg. Co. of Brantford, together with the Slingsby mills nearby, obtain much of their power from a hydraulic canal which takes its water from the Grand River at Wilke's dam. The raceway gives a head of about 15 ft. The hydraulic plant of the Watson Mfg. Co., supplies power to the various motors in the mill which run the textile machinery required in the making of Watson's underwear. Two 48 in. Stillwell water wheels of the vertical type are installed and drive a horizontal shaft of 6 in. diameter through crown gears. One turbine only is used at present, the other being held in reserve and providing for future requirements. A Woodward governor is used for regulating the speed.

The generator is of Canadian General Electric make, type ATB, and is driven at 200 revolutions per minute. At full load it has a capacity of 241 amps at 600 volts. An exciter forms part of the generator, but owing to the extreme vibration of the generator shaft, caused by the crown gears, its use has been discontinued and a separate exciter used. This machine, driven by a small countershaft, has a capacity of 140 amps. at 125 volts and serves not only to excite the a. c. generator, but is also used for lighting and for the preparation of bleaching solution.

The bleaching solution is prepared in a small electrolytic tank. Salt or sodium chloride is added to the water and the electric current liberates the chlorine which goes into solution. This bleaching solution is used in the preparation of the various fabrics which enter into the manufacture of the underwear.

Switchboard

A two panel board serves to control the generator and also makes provision for the use of Hydro-Electric power when necessary. The usual exciter switches and field switches are mounted on the generator panel, and a double throw oil switch throws either the generator or Hydro-Electric energy onto the busses. This panel is provided with three generator ammeters, three ammeters for Hydro, and two voltmeters. A recording steam pressure gauge is also fitted.

Fire Pumps

A Rodney Hunt rotary fire pump, manufactured in Orange, Mass., is driven off the main shaft by means of a friction clutch and Morse chains. This pump is driven at 275 revolutions per minute, and is capable of furnishing four 1 1-8 in. streams at 90 lbs. pressure. The details of the chain drive for this pump may be seen in one of the accompanying illustrations.

The generator room is well lighted and its well-kept appearance, together with the attractive foliage plants, reflect credit on the engineer, Thomas Hurst.

The mill is driven by fourteen motors which drive separate line shafts. Three Otis freight elevators are installed.

Steam Equipmemnt

A 125 horsepower horizontal return tubular boiler supplies the mill with the steam used in the dye-house, for washing and other purposes. This boiler is fitted with rear end Diamond soot blowers and a surface blow off. A Sims closed feed water heater is also installed and Bundy traps return the condensate from the heating system, dryers, etc.

A 45 I.H.P. Wheelock engine is used as a reserve supply of power.

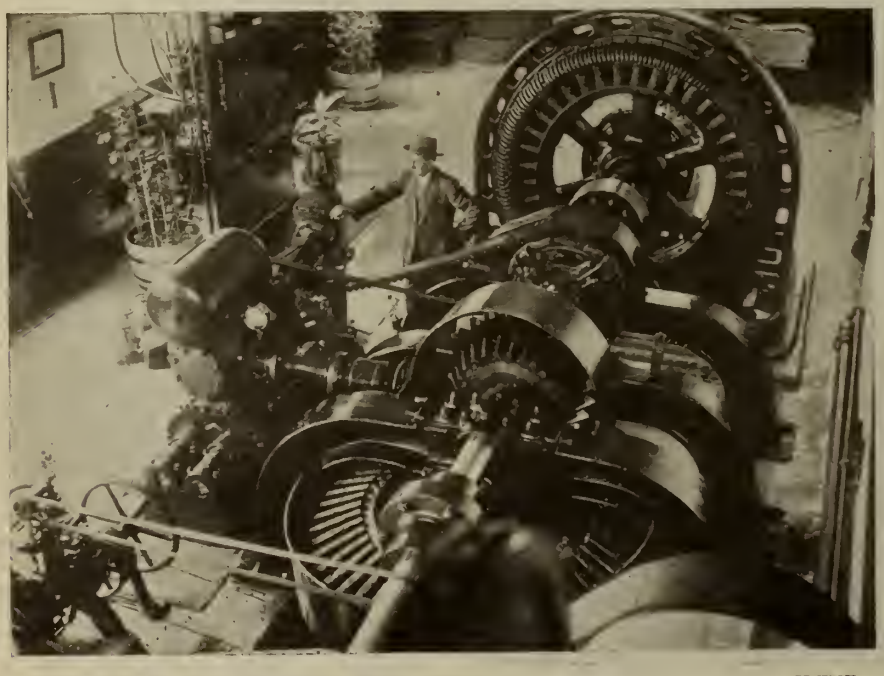
At one time the mill was fitted with two Lancashire boilers. One of these was replaced with the horizontal return tubular boiler, and the other is now used for heating purposes.

Water Softening Plant

While not strictly a part of the power plant equipment a water-softening plant is one of the interesting features of this mill. All the water used for textile purposes in the mill is treated, as it is essential that it be of high purity and as soft as possible. The treated water is also used for all other plant purposes except for the drinking water, and makes an admirable supply for boiler feeding.

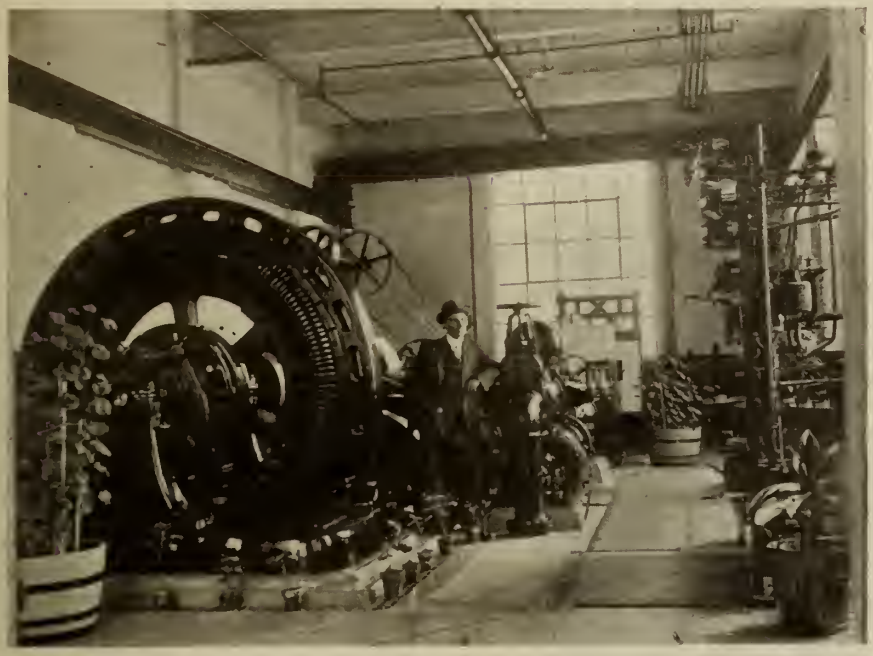
The water-softener and purifier was installed by the International Water Softener and Filter Co., Chicago, and has a capacity of 80,000 Imperial gallons in 24 hours. The water is first treated with alum for the coagulation of organic matter and to facilitate its removal, and is pumped into a settling tank. This tank is 17 ft. in diameter and is 20 ft. high. The entering water and also a mixture of lime and soda enter this tank through an inner chamber, which extends to the bottom of the settling tank, and which has alternate staves cut away for about two feet at the bottom. The entering water and the lime and soda solution thus flow to the bottom of the tank and out through these openings.

In the bottom of the settling tank is a series of pipes having numerous elbows opening downwards; these serve to pick up all sediment and mud and discharge it to waste through a sluice valve manually operated.



WATSON MFG. CO., SHOWING CROWN GEARS TO TURBINE SHAFT AND SILENT CHAIN DRIVE TO FIRE PUMP.

The now softened water passes from this tank to a smaller filtering tank, where it is filtered through sand and is made clear and sparkling.



GENERATOR ROOM, WATSON'S, LTD.

The chemicals used are mixed in a mixing tank, which automatically supplies the proper amount to the settling tank.

FUEL OIL AND ITS APPLICATION

By M. M.

Apart from its superiority to coal for marine propulsion the use of oil on railways is advantageous in countries which are not favorably situated in respect of coal supply. A typical instance is that of the Mexican railway, where conversion from coal to oil has resulted in reductions of 32 per cent. in the weight of fuel consumed per train kilometre and of 40 per cent. in the cost of fuel. The oil can be handed from tank cars to storage tanks, and thence to locomotives for about 0.03 cents per ton, while the average cost of handling coal is about 5 cents. The wastage in handling, between shipment and consumption, (estimated at 8 per cent. to 10 per cent. with coal), is eliminated. No men are required to load upon the engine or clean out ashpans, there are no ashpits to empty, or ashes to be loaded up or hauled away.

In the comparative tests carried out by the Tehuantepec National Railway, the following information was obtained:

The gross weight of train being approximately 500 tons, time getting 180 lb. steam from coal, 150 mins; time getting 180 lbs. steam from oil, 70 mins.; improved speed with oil over coal (average) 16.2 per cent.; improved evaporation per lb. fuel, 5.62 lb. or 90 per cent.; pounds of coal per 100 ton miles, 20.8; pounds of oil per 100 ton miles, 10.3.

The grades on this railway vary from level to 2.15 per cent., with many curves up to 11.5 degrees, where the train's speed is limited to 15 miles per hour.

The output of the boilers could be augmented by 30 per cent. to 100 per cent. by substituting oil for coal. Where used as an auxiliary equipment to coal-fired boilers to meet recurring peak loads, its use not only enables the plant to meet sudden and heavy demands, as in the case of electrical power stations, but many obviate the necessity of putting down additional boilers with the growth of the average output of current.

The perfect smokeless combination of oil fuel would prevent or abate the smoke nuisance in closely populated districts.

On a comparative test run at Wallsend Slipway on coal and oil on a Scotch marine multitubular type boiler, the following results were obtained:

Fuel Oil

Specific gravity at 60 degrees, F., 0.953; viscosity at 100 degrees F., (red No. 1), 2,130 secs.; flash point, (close), 160 degrees F., (above); calorific value in b.t.u., 18,430.

Water Evaporated

Pounds of water per lb. of oil, 12.15; lbs. of water per lb. of oil (from and at 212 degrees F.), 14.38; boiler efficiency, 73.37 per cent.

Coal

Calorific value in b.t.u., 14,432.

Water Evaporated

Pounds of water per lb. of coal, 7.76; lbs. of water per lb. of coal (from and at 212 degrees F.), 9.31; boiler efficiency, 62.28 per cent.

Efficiencies as high as 84.8 per cent. have been obtained on Scotch marine type boilers, using Mexican fuel oil, with the pressure system of oil burning.

At a large London factory Lancashire boilers have been converted, and the following comparative figures obtained:

	Fuel Oil	Coal
Calorific value	18,750 b.t.u.	11,451 b.t.u.
Evaporation per lb.	14.44 lb.	7.22 lb.

Do. per sq. ft. heating surface 7 lb., 3.31 lb.

In the United States a large series of actual working temperature tests have shown that with coal the thermal efficiency of boilers varies from 66.6 per cent. to 68.1 per cent., with oil from 80.6 per cent. to 81.5 per cent.

In Great Britain fuel oil is used in industrial furnaces for such processes as billet heating, metal melting, riveting bolt and nut making, and the manufacture of glass bottles. Of the three systems of burners for oil fuel the pressure jet system, in which the atomizing agent is pump pressure and steam temperature, has been developed during the last 10 years to such an extent that it is now recognized as the most economical system for use under land and marine boilers, and is being rapidly developed for locomotive purposes. The oil is drawn from the storage tanks by a steam pump through suction strainers, and delivered through heaters and discharge strainers to the oil fuel burners.

A point which usually appeals to every works manager is the fact that when utilizing coal fuel the size of the furnace is reduced by 30 per cent., and the workings are occupied by a furnace and its adjacent machines is only about 50 per cent. of that of coal fired furnace, where a stack of coal occupies a certain amount of space in front and the ashes another space behind. Another interesting feature is that many metal melting furnaces have either scrapped their coke fired furnaces or converted them to gas or oil.

In the early years of this century a French engineer introduced the subject of oil as an auxiliary. The main advantage of auxiliary firing lies in being able to obtain at will a large increase in the power of boilers. The combustion of the petroleum does not in any way prejudicially affect that of coal; in fact, by the introduction of jets of petroleum the condition and efficiency of combustion are improved by a more complete mixture of the gases. It is, therefore, not correct to consider the evaporative power of coal as identical when passing from ordinary auxiliary firing.

Admitting this as a principle, and supposing the quantity of water evaporated by the coal to be constant, the extra evaporation due to the better mixing of the gases is credited to the petroleum.

In several evaporative trials made on the same boiler of a French navy ship, when coal alone was burnt at the rate of 18.8 lb. per sq. ft. of grate area per hr., the water evaporated per lb. was 9.05 lb. With a mixture of coal and 45 per cent. oil, the corresponding figure was 11,341 lb., with a mixture of the coal and 64 per cent. oil 14.12 lb. In this last test the efficiency of the mixture was higher than when burning petroleum only.

These tests served as a basis for further experiment, about four years ago, by power station engineers. Their theory

was that a poorer class of coal could be used in conjunction with oil fuel. When used alone the inferior coal tended to cake on the links of the chain grate stokers, thereby retarding the necessary quantity of air from being drawn through the bars to complete combustion. The result was a smoldering mass, which travelled slowly along to bars and was dumped into the ashpit as a partly consumed coal. On analysis this ash would probably be found to contain a very high percentage of combustible matter. Therefore a very much higher quantity of coal was burned per hour to maintain, say rated evaporation.

The theory was that when fuel oil was applied the combustible gases arising from the coal fuel bed were quickly ignited, causing the top of this mass to become much more incandescent, and thereby tending to aerate the bottom mass, which would allow sufficient air to be drawn through to complete the combustion of the inferior coal.

Sufficient interest was taken in this theory for a large London power station to give sanction for tests to be carried out under a coal fired Sterling water tube boiler. One burner was introduced into each side of the boiler approximating about 25 per cent from the back of the grate, the burners being opposite each other. The oil was stored in an overhead tank, capable of holding three or four days' supply. It gravitated to the burners, which were of the Kermode steam-jet type, operating with steam as an atomizing agent at a pressure of about 25 lbs. per sq. in.

The first test was carried out on a nutty slack, having a calorific value of 10,400 b.t.u., and a boiler efficiency of 69.25 per cent. was obtained. The temperature of the combustion chamber was 2,648 degrees F., and uptake 660 degrees F.

The final of a series of experimental mixed burning tests was carried out on a mixture of nutty slack, having a calorific value of 10,300 b.t.u., with Mexican fuel oil, having a calorific value of 18,750 b.t.u. A boiler efficiency of 74 per cent. was obtained. The temperature of the combustion chamber was 2,850 deg. Fahr., and uptake 628 deg. Fahr. The proportion of oil to coal on a B.t.u. basis was 8 per cent., and on a weight basis 4.96 per cent. The comparative costs were—with coal only 2.8; with the mixture mentioned, 2.62, showing a monetary saving of 6 per cent.

The tests showed that with oil at a cost of 2½ times the cost of coal, and burning in the aforementioned percentages, a saving is effected which should induce power station engineers to consider adopting this method of firing in the super-power stations of the future.

As an example of the saving effected, the following figures have been given by a well-known firm of bolt and nut makers in the Manchester district:

Gas costs 1s. per 1,000 cu. ft., less 5 per cent.; consumption 450 cu. ft. per hour; temperature in furnace, 1,750 deg.; size of bolts, ⅜ of an inch dia. to ⅝ of an inch dia., calorific value; gas equal 660 B.t.u. per cu. ft.

Comparing with oil on B.t.u. basis for ten hours' working, then

$$\frac{450 \times 10 \times 660}{18{,}750} = 159.5 \text{ lb. oil} = 16.7 \text{ gals.}$$

Cost of gas for 10 hours

$$= \frac{450 \times 10}{1{,}000} = 4\text{s. } 6\text{d. less } 5\% = 51.3\text{d.}$$

Cost of oil at say 2¾d. per gal. $= 16.7 \times 2.75 = 45.9$.

Saving per day by using oil = 5.4d.

Saving per year of 300 days = £6 15s. per furnace.

Figures given in the Manchester district with regard to bolt making:

One furnace feeds two bolt-making machines.

The output of these two machines is four tons per day.

	£	s.	d.
To obtain this output, 1 ton 10 cwt. of coal is used at 12s. per ton	0	18	0
Using oil at 5 gals. per hour (10 hours per day) at 2¾d. per gal. = 1s. 2d. × 10	0	11	8
They have seven furnaces in operation. This means that they pay out for coal in six days per week (12s. per ton coal; one furnace burns 1 ton 10 cwt.) 18s. × 7 × 8	37	16	0
Oil consumption per week of 53 hours at 5 gals. per hour (7 furnaces) 5 × 55 × 7 = 1,925 gals.; 1,925 gals. at 2¾d. per gal. oil	22	1	1
Saving in favor of oil	15	14	10

Comparative tests between coke furnace (Baumann) and oil furnace (Buess).

Tables of Costs for a Production of 300 Tons (Baumann)

	£	s.	d.
Coke consumption, 12.3 per cent., 36 tons 18 cwt. at 30s. per ton	53	7	0
Power 960 hours, at 5s. 6d. per hour	13	6	8
Crucibles, including stands, average life 40 charges for 300 tons, 1,500 charges, 37½ crucibles at 50s. each	93	15	0
Lining four times at 30s.	6	0	0
Wages for furnacemen, 125 days at 8s. 6d. per day	53	2	6
Loss in melting, average percentage of 1.62 per cent., 4 tons 19 cwt.	336	4	0
Total	£555	15	2

Buess

	£	s.	d.
Oil consumption at 9.8 per cent., 29½ tons at 60s.	88	10	0
Power, 1,380 hrs. at 5s. 6d., 8 h.p.	38	6	8
Cost of crucibles, including stand, average life 40 charges per 300 tons, 1,500 charges, 37½ crucibles, at 41s	76	17	6
Cost of lining twice and one cover	5	0	0
Wages of furnacemen (7½ tons cost 18s.), 300 tons	36	0	0
Loss in melting at average percentage 0.3 per cent., 18 cwt. 7½ lbs.	66	0	0

Baumann	555	15	2
Buess	310	14	2
Total	£245	1	0

PRESSURE ON FOUNDATIONS OF TALL CHIMNEY

It is often necessary to calculate the pressure on the subsoil of the foundation of a chimney stack. Taking a circular steel chimney stack 120 feet high by 9 feet diameter, with a weight of about 27 tons, as an ordinary modern works' chimney, it is interesting to find the total direct load on the foundation, particularly where the chief difficulty is the question of wind pressure. The particular chimney which was taken as an average stands on a brick base 20 feet square by 12 feet high, with a circular hole 9 feet in diameter for the full height of 12 feet, and the flue entrance on one side was about 9 feet high by 8 feet wide.

The total direct load on the foundations will consist of 27 tons for the steel chimney 9 ft. dia. and 120 ft. high; added to 20 ft. by 20 ft. by 12 ft. high for brick base, with 9 ft. hole through it = 4.037 cub. ft. at 112 ft. per cubic ft. — 202 tons; added to 24 ft. by 24 ft. by 3 ft. concrete slab = 1,728 cub. ft. at 144 lb. per cub. ft. = 111 tons; together 27 + 202 + 111 = 340 tons. The wind pressure may be taken as 35 lbs. per sq. ft. acting on the diametrical plane of the chimney and base. The moment of the wind pressure about underside of concrete will be

$$\frac{35 \times 9 \times 120}{2{,}240} \times \left(\frac{120}{2} + 12 + 3 \right) =$$

1,267 ton-ft.

The moment of the wind pressure on the brick base about the underside of the concrete will be

$$\frac{35 \times 20 \times 12}{2{,}240} + \left(\frac{12}{2} + 3 \right) = 32 \text{ ton-ft.}$$

or total amount M — 1267 + 32 = 1,299, say 1,300 ton-ft. To get the distribution of the load over the foundation we have $\frac{W}{A} + \frac{M}{Z}$ where W = direct load.

A = area; M = moment; Z = section modulus of base = 1-6bd². Then

$$\frac{W}{A} + \frac{M}{Z} = \frac{340}{24 \times 24} + \frac{1300}{1\text{-}6 \times 24 \times 24^2} =$$

.591 + .564 = 1.155 tons per sq. ft. maximum compression on soil, which will be on the leeward side; also = .591 — .564 = 0.027 tons per sq. ft. minimum compression of soil, which will be on the windward side.—M.M.

Town of Newmarket Scene of Serious Explosion

Rear Head of Steam Drum in a Babcock & Wilcox Water Tube Boiler Blows Out—Accident Attended With Loss of Life, and Severe Injuries, Besides Considerable Property Damage

By T. H. FENNER, Editor Marine Engineering

ON the morning of June 12, at about 9.30 a.m., an explosion occurred of a drum in a Babcock & Wilcox water-tube boiler, in the wood-working factory of Wm. Cane and Sons, Newmarket, Ontario. The rear drum head ruptured around the flange where it was riveted to the drum, and the escaping steam carried death and destruction in its path.

The boiler room was on the ground level, thus bringing the drums to the level of the floor above. The illustration shows how this section of the building was completely wrecked, the people employed there being blown out on the street, and severely burned, as well as hurt by the fall. Five of the victims have died since, and eight others are making slow progress towards recovery.

The drum head was defective for about three-quarters of its circumference, but the deteriorating effect had not spread to the portion which was normally over the water level. This portion of the head, being of its original tenacity and ductility, opposed sufficient resistance to cause the head to turn upwards as on a hinge, and resulted in it being deflected, when it did shear, to a course directly opposite to the escaping steam. It rose up through the roof, sailed over the boiler room, and landed out in the yard at the back of the building, almost burying itself in the soft sawdust-covered ground.

VIEW OF DRUM SHOWING FRACTURE AND TORN PORTION OF DRUM HEAD AT TOP.

GENERAL VIEW SHOWING HAVOC CREATED

Immediately behind the boiler room were situated the drying kilns where the green lumber was made ready for manufacturing operations. When the explosion took place, some of the escaping steam found its way into the setting, blew the fire doors open, and sent a blast of flame and hot sawdust into the drying kilns, setting them on fire. The two firemen were severely burned by this blast of flame, followed by the steam, and the engineer also received some of it, injuring him severely.

Prompt measures were taken to fight the fire and relieve the sufferings of the injured, but it was several hours before the fire was finally subdued.

The Cause of the Failure

The writer visited the scene of the explosion the morning following the occurrence, and was enabled to make a fairly close examination of the boiler, externally. The boiler was a 14-tube wide by 9 high Babcock & Wilcox water-tube boiler of the ordinary stationary type. Looking from the front it was the left hand drum that suffered, and the rear head. This head contained the manhole opening, and there was also a two-inch pipe entering into the drum, evidently used as a surface blow off.

The steam connections of the boiler consisted of a main stop valve, 6 in. diameter, on the back end, and an auxiliary valve for supplying steam to the dry kilns, etc., on the front, and each drum carried the usual 4-inch safety valve.

As before mentioned, the fractured head showed an area of defective metal extending round the circumference from about 45 deg. above the centre line, one each side. The remaining portion of the metal had preserved its original qualities, as shown by the elongation that took place before it parted. Now, before going any further, it occurs to the mind of the observer to ask this question: What was the particular circumstance that caused the head to break away at that particular moment, and on the other hand, why had it not parted before? It is possible to make deductions without claiming that events were

SHOWING STEAM PIPE PARTED FROM ELBOW AND DEFLECTION OF EQUALIZING PIPE AND FITTING

as deduced, but at least to find a starting point.

It will be seen from the illustration that the equalizing header, on which the 6 in. connection was mounted, has been bent back from the normal position about 20 deg. The 6 in. steam pipe has been drawn clean out of the elbow, the thread in the elbow being torn off about five threads back. A further circumstance is that from the appearance of the brickwork in front of the boiler, the drum did not move in its setting in a longitudinal direction to any great extent. Examining these facts, a possible solution presents itself. The fracture was not continuously through the rivet holes, but followed an irregular line, in some cases leaving a considerable amount of metal around the rivet. Chiefly the line followed the line of rivets.

The fact that the fracture had apparently reached its limit, and that for some time had not made any progress, is indicated by the appearance of the fractured edges. This leads one to think that failing a sudden shock the head might have held indefinitely, the frictional hold of the rivet heads being sufficient to resist the steam pressure. This would be quite feasible in a boiler with the quality of workmanship so evident in the B. & W.

If we accept this hypothesis we must look for the second factor: "What was the nature of the sudden shock?"

Let us turn to the steam pipe again. The elbow faced to the front end of the boiler. The steam escaping from the drum rushed from front to rear. Tracing the causes of the steam pipe and elbow parting company, assume that the head of the drum blew out first. The recoil of the escaping steam would cause the drum to jump forward, pressing the elbow on to the pipe and either bursting the elbow, or shoving the whole length of steam pipe and connections in front of it. Obviously this did not happen. Instead of that, the elbow shows a thread pulled out. In the light of this, would it not be reasonable to think that the pipe pulled out of the elbow before the explosion, and that the sudden escape of steam supplied the necessary shock to cause the final rupture of the head? The writer thinks it would, and offers the suggestion for what it is worth.

VIEW DRUM HEAD SHOWING FRACTURE

The Primary Cause

As to the initial cause of the defect, it is not possible to form an opinion with the evidence at hand. The embrittling effect of free hydrogen on steel has been mooted as the cause, and it may well be that a searching investigation will undoubtedly be made by the makers of the boilers in conjunction with the inspection authorities.

Full particulars of this investigation will be available to readers of the POWER HOUSE in due course.

WATER STORAGE ON ST. MAURICE RIVER

New Power Developments Made Possible By La Loutre Reservoir

The great benefit derived from water storage is soon to be further demonstrated on the St. Maurice River, where a large water-power undertaking will soon be started.

The increased power made possible at the various sites on this river by the La Loutre Reservoir, the largest but one in the world, is a strong incentive to prospective power users. It is estimated that the conserved water thus made available represents a total increase of over 500,000 h.p.

The proposed development above referred to is reported to be in connection with the operations of the St. Maurice Paper Company, the latter having leased two sites in the lower portion of the river, known as Les Forges and La Gabelle. It is intended to combine these two, giving a total effective head of 33 feet, while the regulated flow from the La Loutre reservoir increases the power now available at this site, namely 20,000 h.p., to 42,000 h.p.

Another proposition reported in this connection is the construction of a hydro-electric plant utilizing the combined site of La Gabelle and Les Gres, the latter site being controlled by the Shawinigan Water & Power Company. The latter power company would carry out the development and supply hydro-electric power to the St. Maurice Paper Company under a special contract.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Readers are invited to send in answers to these problems, as they have been chosen for their interest and application to the practical side of power plant operation.

Perhaps you, too, have some pet problems, or hard nuts which you would like to ask your fellow engineers; if so, send them along for the benefit of others.

Answers, together with the original question, will be published in the issues following the appearance of the question.

Questions Before The House

24.—(a) Name the various forms of rivet heads used in boiler construction; (b) How are rivet heads formed? (c) In what respect has machine riveting advantages over other processes of riveting?

25.—(a) What is a lap joint?; (b) What is a butt joint?; (c) Distinguish between single and double-riveted joints?; (d) Distinguish between chain-riveted and staggered-riveted joints?

26.—Which is the strongest type of the ordinary riveted joints?

27.—What precautions are taken in locating the longitudinal seams of externally-fired boilers, and also of cylindrical furnace flues of internally-fired boilers?

28.—What objection can be urged against constructing the fire-door hole of a locomotive type boiler by flanging the inner and outer sheets to a single curve?

Answers to Questions In Last Issue

Question 13.—If your safety valve has been blowing off at 100 lbs. and now commences to blow at 80 lbs., what would you do to remedy the same, in the event of the steam gauge indicating 120 lbs. before the safety began to blow? What would you consider the possible cause, and what would you do to remedy the same? What action would you take?

Answer.—I would find out if my safety valve was clean or dirty and would try blowing off by hand in the morning when it might be stuck to the seat. I would certainly have the safety valve blow off at the pressure for which it was set if at all possible.

Question 16.—Explain fully the construction and action of a safety valve spring-loaded pop. In what does it differ from the other ordinary spring-loaded valve? What is the advantage of the pop over the ordinary? How does the connecting of a long discharge pipe affect its working.

Answer.—A spring-loaded safety valve is mostly used on large boilers, and a long discharge is not as satisfactory as a short outlet. There is too much condensation and back pressure.

Question 20.—If you were in charge of a steam plant where there was boiler power to spare, but the engine in its present condition was fully loaded, what would you do to increase the power of the engine in order to run extra machinery, assuming that the boiler pressure can not be raised, and that all parts of the engine are strong enough to carry the extra load?

Answer.—I would run the engine a little faster by adjusting governor. If this did not prove satisfactory I would change the pulley on the line shaft to compensate for increased speed of engine.

Editor's Note.——Our correspondent has overlooked increasing the cut-off to give higher mean effective pressure.

Question 22.—What is the safety head of an ammoniac compressor? What purpose does it serve, and how is it constructed? What precautions are necessary in taking compressor cylinder apart in order to prevent injury from inhaling ammoniac gas, if this gas should be inhaled to such an extent that a person becomes unconscious, what action would you take to save him?

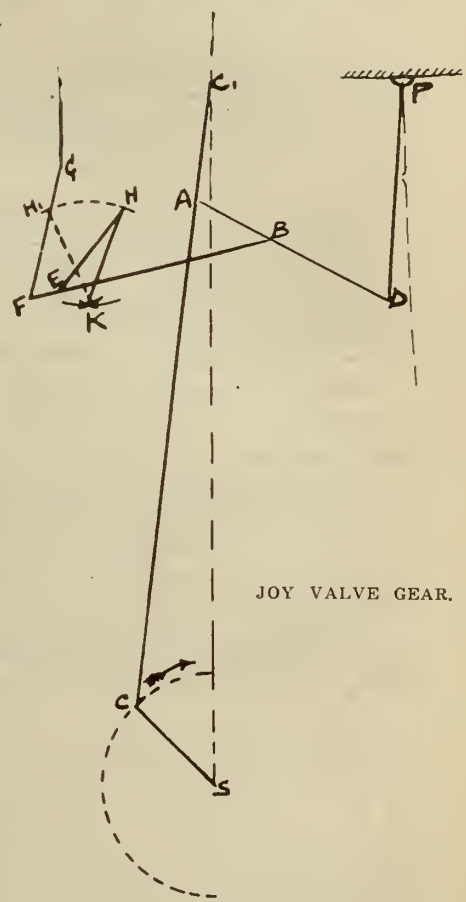
Answer.—In taking cylinder head off, see that the machine is free by turning flywheel by hand. Discharge the machine and open windows in compressor room. Close expansion valves if person should be overcome by gas.

Toronto J. Q.

Reader's Query

Question.—An engine fitted with Joy valve gear is out of order. Suspended and compensating links, also lever connecting compensating links to valve rod, all on the scrap heap. I want to know how to get the length of the different rods, etc., so that when I erect engine valve gear will be O.K.—G. A., Toronto.

Answer.—The following diagram proportions are as below for the correct functioning of a Joy valve gear.



JOY VALVE GEAR.

$$\frac{C\ A}{C\ C} = .2 \text{ to } .23$$

$$\frac{A\ D}{C\ S} = 1.4 \text{ to } 1.5$$

$$\frac{B\ D}{A\ D} = 05. \text{ to } 0.6$$

$$\frac{D\ P}{C\ S} = 1.4 \text{ to } 1.5$$

$$\frac{B\ E}{C\ S} = 1.5 \text{ to } 1.65$$

$$\frac{E\ F}{C\ S} = 0.2 \text{ to } 0.3$$

$$\frac{E\ H}{C\ S} = 0.8 \text{ to } 1.0$$

$$\frac{F\ G}{C\ S} = 1.0 \text{ to } 2.5$$

A Baffling Proposition

WHILE in many instances it is comparatively easy to determine the direct cause of boiler failure and explosion, the history of the events leading up to the rupture are more or less obscure and somewhat difficult to determine. Such seems to be the case in the recent explosion at Newmarket, where five and possibly more lives have been lost. The boilers themselves, made by one of the most widely known firms, embodied careful workmanship and were far removed from the type of boiler usually featuring in such accidents. Monthly cleaning-down seems to have been practised, inspection was in the hands of a reputable insurance company, and the boiler at the time of the accident was notably free from scale and evidences of corrosion.

The failure in itself was due to a crack existing in the rear head of one of the drums and which extended, roughly speaking, throughout that part of the circumference below the water line. The remainder of the head showed, by the tear made when it parted company with the boiler, the excellent quality of the steel and its freedom from flaws.

While the immediate cause of the explosion is easily determined, it is in the history of the crack that the true explanation of the accident must be found. The location of the crack immediately outside the rivet holes, and the entire absence of pitting or other forms of corrosion render usual explanations untenable, and the character of the flaw which indicates crystallization necessitates other considerations.

Of late years obscure chemical phenomena occurring in the operation of boilers have received attention, and it is possible that the embrittling action of sodium salts through the action of liberated hydrogen caused the initial failure of the plate.

Trouble has been experienced elsewhere due to this cause, and if such failures become prevalent it will add one more burden to the load of vigilance carried by the operating engineer.

Thirtieth C.A.S.E. Convention

THE established custom of engineering societies and other like organizations of holding conventions each year has much to commend it. And while conventions are primarily essential for the transaction of business relating to the organization, the discussion of matters affecting the welfare and advancement of members in their avocation and otherwise often proves equally valuable.

Such is the convention of the Canadian Association of Stationary Engineers which takes place at Brantford during the present month With the cessation of war activities, the engineer enters upon a period less marked perhaps by hectic activity, but with many of the conditions imposed by war still prevailing. Need for economy in fuel is still evident and with this necessity comes the continued advancement of the power plant and its operator to a higher state of efficiency. The papers of a technical nature which will be given hold promise of being very instructive and useful.

The value of such occasions as these for strengthening the bond of friendship amongst members is well known and social events and plant visitations form an attractive feature. Brantford's power plants are numerous and are well cared for, while her various parks and other recreation spots are well adapted for the entertainment of visiting conventions.

THERE'S no chance for any reduction in the price of coal, and coal dealers are even advising people to burn egg coal in their furnaces. Firing the average furnace with egg coal is about as entertaining and as unsatisfactory as eating peas with a knife.

* * *

HAVING won the war, and made the world safe for democracy, the nations are now doubling up their standing armies and looking over the new designs in guns and munitions.

* * *

TORONTO relief firemen, boiler washers and helpers, chemical attendants, outside attendants, outside coal and ash men presented to the mayor a request for an increase in their weekly wage from $25 to $28 a week. Old H. C. of L. is always hanging around, waiting to lead in a new deputation.

Association and Personal

Program of Convention C.A.S.E., Brantford, June 23, 24, 25 and 26

The 30th Annual Convention of the Canadian Association of Stationary Engineers will be held at Brantford, June 23rd, 24th, 25th and 26th, 1919. The following programme has been arranged:—

Monday, June 23rd—Installing Exhibits (All Day)

3.00 p.m.—Meeting of C.A.S.E. Executive.

7.30 p.m.—Chalk talk on Piston Valve Setting, by J. W. A. Drummond, Drumheller, Alberta.

8.15 p.m.—Power Plant Accessories, by S. Balmfirth, Toronto.

9.00 p.m.—Illustrated lecture on Steam Heating, by E. T. Flanagan, Toronto.

Tuesday, June 24

10.00 a.m.—Official opening.
Welcome to Brantford, by Mayor Morrison McBride.
W. Welsh, President Brantford Lodge, and D. L. Webster, Secretary Brantford Convention Committee.
Reply by W. Cooke, President C.A.S.E.; C. N. Schrag, President Exhibitors' Association; Lieut. L. Archibald, Past President Exhibitors' Association; Fred W. Raven, Secretary N.A.S.E.; D. N. Medcalf, Chief Boiler Inspector for Ontario; Fred R. Low, Editor of *Power;* W. C. McGhie, Chairman Engineers' License Board for Ontario, and C. Z. Wise, Educational Secretary N.A.S.E.

11.30 a.m.—Meeting C.A.S.E. Excutive.

12.30 p.m.—Lunch.

2.00 p.m.—Meeting C.A.S.E. Executive.

2.30 a.m.—Ladies' trip through some of Brantford's factories.

7.30 p.m.—Educational Session and Smoker (men only).

7.30 p.m.—Illustrated lecture on Generators, by C. J. Porter, Hamilton.

8.15 p.m.—Address by Fred W. Raven, Chicago.

8.45 .p.m.—Causes of Boiler Failure, by D. N. Medcalf, Chief Boiler Inspector for Ontario.
Song by Jack Armour

9.30 p.m.—Illustrated Lecture on Turbines, by J. M. Brown, Hamilton.

8.00 p.m.—Theatre party for the ladies.

Wednesday, June 25

9.00 a.m.—C.A.S.E. Executive session in Convention Hall. Exhibition Hall open morning and evening (not afternoon).

2.30 p.m.—The Engineers and their friends will be the guests of the Exhibitors' Association at Mohawk Park. Special cars will be provided to take the party to the park. Ice cream and peanuts will be supplied. There will be an excellent programme of sport with valuable prizes supplied by the Exhibitors' Association.

5.45 p.m.—Cars leave the park for the city.

8.00 p.m.—Meeting in Convention Hall, open to Engineers and friends.
Presentation of prizes.
Address by Dr. W. A. Riddell, Superintendent Trades and Labor Branch for Ontario.
Prize drawing contest.
Unique sale of curios in aid of a Brantford institution.
Address by W. C. McGhie.
Music—vocal and instrumental, including songs by E. F. Hetherington and E. B. Curzon, two popular exhibitors.
Speech by Jack Armour.
Recitations, etc.

Thursday, June 26

9.00 a.m.—C.A.S.E. Executive sessions.
Exhibition Hall open all day (not in evening).

10.30 a.m.—Annual meeting Exhibitors' Association.

11.30 a.m.—Exhibitors' Association entertains the Grand Lodge in Exhibition Hall, demonstrating exhibits and distributing souvenirs, etc.

2.00 p.m.—Lecture by C. C. Carison, M.E., Waterous Engine Works, Brantford.

3.00 p.m.—Installation of C.A.S.E. officers in open meeting.
Installation of officers of Ladies' Auxiliary.

8.00 p.m.—Annual Engineers' Ball in the Masonic Hall, under the auspices of the Brantford Lodge. Tickets, $1.00. Ladies free. A caterer will serve refreshments, which will be extra.

The Entertainment Committee consists of E. B. Curzon (chairman), Earl F. Hetherington, Geo. Moll and G. C. Keith in co-operation with C.A.S.E. Executive and Brantford Lodge.

Submarine Indemnities

AT an international conference of transport workers held in Amsterdam recently the Belgian delegate introduced the following motion:

The International Conference of Transport Workers, taking into consideration that approximately twenty-two thousand seamen of all nationalities have been murdered in consequence of submarine warfare, appeals to the German Government to grant full indemnity to the families of these murdered seamen. The report says that the German delegates expressed approval of this motion.

A PENNSYLVANIA peanut and fruit stand man left an estate of $30,000. The man who stows away a nickel's worth of peanuts in his vest pocket will be willing to believe this.

* * *

ON A Detroit street a doctor, undertaker and tombstone maker have their establishments side by side. As the efficiency man in the machine shop would say, the sequence of operations is admirably arranged.

Plant Equipment Exhibitors' Association Feature

Efforts of Manufacturers and Dealers Insure Interesting and Instructive Display—Featuring Power Plant Equipment and Operating Necessities

AS in former years a feature of the annual convention of the Canadian Association of Stationary Engineers will be the exhibition of power house apparatus, accessories and supplies, organized by the Exhibitors' Association.

While the urgent need for fuel economy from a patriotic standpoint has passed, the lessons learned from the practice of rigid economy under war conditions have remained and the necessity for economical power production yet remains. This fact lends interest to the various exhibits and will color many of the addresses and discussions which will take place.

As indicated in a previous issue of POWER HOUSE, the convention opens on Tuesday, June 24, the opening ceremony in Convention Hall being performed by Mayor McBride, following which the appointments of the various committees will take place.

Tuesday afternoon will be given over to an executive meeting and a trip for the ladies through various Brantford factories as guests of the C.A.S.E. executive. Tuesday evening will be devoted to an educational session and smoker for the men and a theatre party for the ladies arranged by the Brantford Lodge. The educational features of this session promise to be of high value.

The program for Wednesday, as will be seen above, includes a picnic at Mohawk Park, one of Brantford's beauty spots on the shore of what is known as Mohawk Lake. The prizes for the sporting events of the day will be donated by the Exhibitors' Association. These prizes will be presented at a meeting in Convention Hall at which entertainment is provided.

The final event on Thursday is the Annual Engineers' Ball in the Masonic Hall, under the auspices of the Brantford Lodge.

Brantford as a convention city is admirably suited for the double purpose of holding business and educational sessions and for the entertainment of visiting members. Convenient of access by railroad and offering many attractions to the engineer, the activities and labor of the local lodge, under Mr. D. S. Webster, should meet with a record of attendance.

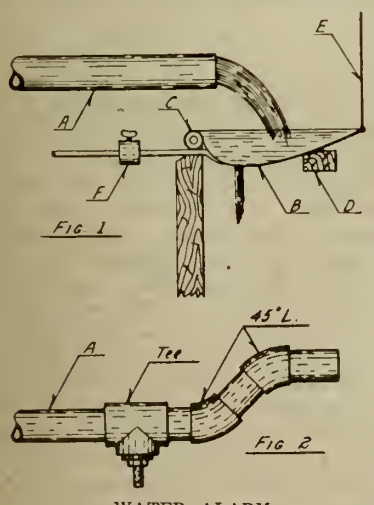
The Exhibitors' Association is under the presidency of C. N. Schrag, of the Equipment Specialties Co., Toronto. As in former years, G. C. Keith, editor of *Canadian Manufacturer*, will discharge the duties of secretary, the other officers being Wm. Welsh, Brantford, honorary president; C. B. Turner, Toronto, 2nd vice-president; E. B. Curzon, Darling Bros., Montreal, chairman entertainment committee; L. H. Rumage, V. O. Anderson Co., Buffalo, assistant secretary; Jas. S. Mock, Jenkins Bros., Montreal, 1st vice-president; L. Archibald, Dart Union Co., Toronto, past president; B. G. Newton, manager THE POWER HOUSE, Toronto, treasurer; H. J. Remshaw, Garlock Packing Co., Hamilton, chairman reception committee; Arthur Belton, Jas. Morrison Brass Mfg. Co., Toronto, chairman exhibit committee.

The Operators' Point of View

ELECTRIC SIGNAL

An electrical signal device to give warning when the flow from the discharge pipe of a pump stops, or, if preferred, when it reaches a certain predetermined allowable minimum, may be rigged providing the pump is discharging to the atmosphere with a few inches of drop for the water after it leaves the discharge pipe. As, for instance, when going to waste for dumps in mining, or prospecting practice, or when filling tanks from above, etc.

A, Fig. 1, is the discharge pipe. B is a somewhat ladle-shaped apron, onto which the water falls. It is hinged at C, and when full of water is supported at D. It has a hole in the bottom just large enough to empty the apron quickly if water ceases to flow into it from A. E is a galvanized iron wire, which is attached to the outer end of B and to a spring above. Just above this spring again is an ordinary push button in a bell wire circuit, but the button is placed as though fastened to a ceiling. Adjust the spring so that so long as water enough flows to keep the apron full in spite of the hole in the bottom,



WATER ALARM.

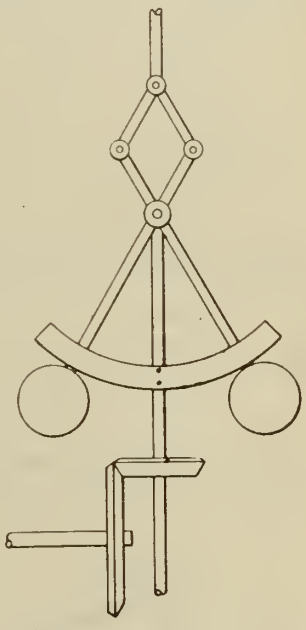
the weight of the apron and the water in it will hold the spring down, but if the discharge at A ceases, thus allowing B to empty through the said hole in the bottom, this allows the spring above to rise and press the button, thus closing the circuit and ringing the bell. If the margin between rising and not rising is too small to make the spring action reliable, an apron holding a little more water is required. It is the weight of water in the apron (together with some force from the fall), that holds the spring down. With no water in the apron the spring should positively rise. If it will not, and the apron is as light as seems consistent, then a stronger spring is required, or a small counter balance weight F may be added to partially offset the weight of the empty apron. This weight may be a sliding one on a small beam and having a set-screw to hold it where placed, thus making its effect adjustable.

By the above method the bell only rings when the pump fails to discharge enough water to keep the apron full. To have it ring when the discharge has fallen to the lowest allowable discharge, put a tee on the end of the discharge pipe and turn the side outlet to one side or downwards. Into the end of the tee screw a 45° street elbow, or else a nipple, and an ordinary 45° elbow and turn the elbow to pointing upwards; then insert another short piece of pipe and add another 45° elbow, its outlet pointing horizontally, and, if desired for purposes of protecting the screw threads, another nipple may be added. See Fig. 2. Place the apron under this, as was shown under A, Fig. 1. Now, bush down the side outlet of the tee until what experiment proves to be the minimum allowable, discharge will just escape at the tee without any overflow into the apron. The discharge from the tee, of course, does not go to the apron. Now, so long as enough water is discharged to keep the full stream running from the tee, and, in addition to this, keep the apron full, the electric circuit will remain open. If the water can all escape through the tee, the apron will empty itself and allow the spring to rise, thus closing the circuit and causing the bell to ring.—J. E. M.

BELL ALARM OF CONVEYORS

By J. E. McCormack

To arrange for warning by electricity when a conveyor stops, procure a cheap set of governors such as would be suitable for use on a small steam engine. Remove the valve chamber and take the valve from its spindle. Set the remainder where you can drive it from a pulley placed on the conveyor shaft. Choose the shaft that stops when the conveyor stops. Most governors will, when relieved of the duty of compressing a spring or raising a weight, raise or lower the valve spindle at comparatively low rates of speed. This feature is a necessary one to secure. Now run your wires to an easily operated yet reliable self-closing spring electric contact, where the valve spindle of the governor will



CONVEYOR BELT ALARM.

hold it open while the governor is in motion. In case the governor stops then the spindle will cease to touch and the spring will close the contact and thus the circuit, and ring the bell. To economize in current, do not forget to open the switch when shutting down at night. If you are in the habit of remaining behind until the machinery stops, the bell ringing will remind you of the switch.

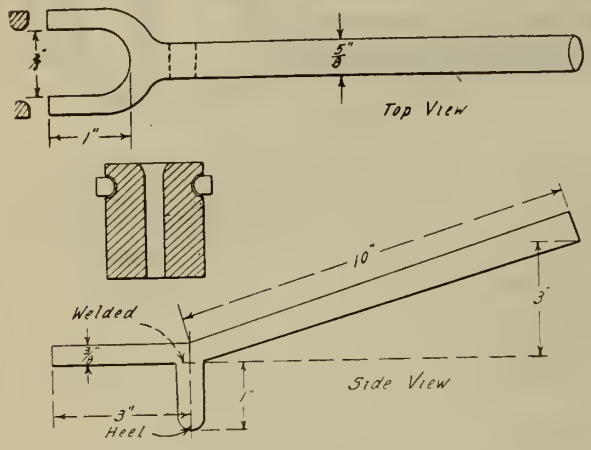
The sketch indicates a simple form of governor which may be easily constructed from two small gear wheels, some small shafting, and rods, bolts and a small pulley. Probably the patent, if any, has been expired for years. The balls may be molded from lead or babbitt, and if cubical will do almost as well if easier made that way. The appearance will be the worst feature perhaps. It will be seen that the arms cross each other and swing in a slotted sector. They are shown in "Mechanical Movements, Powers and Devices," by Gardner D. Hiscox, M.E., a very good book for mechanics to own. If this type of governor were used the spring contact used should be self-opening and placed above so the governor rod would push up on it, shoving it shut when the governors quit revolving: a common push button serving in this case.

A KNOB REMOVER

J. L. Martin

(Copyright. All rights reserved.)

We have used a tool, made about as shown in the accompanying sketch, for removing knobs in knob-and-tube jobs and if properly manipulated we find it quite successful. We had our remover made by a local blacksmith from a rough pencil drawing.

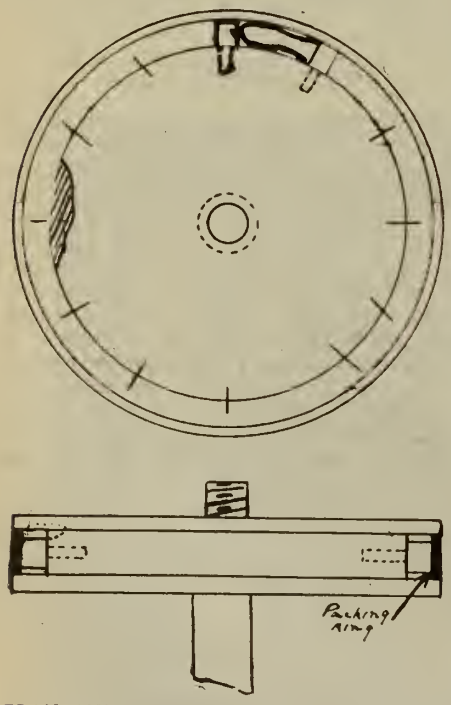


KNOB REMOVER.

INTERESTING PISTON TROUBLE

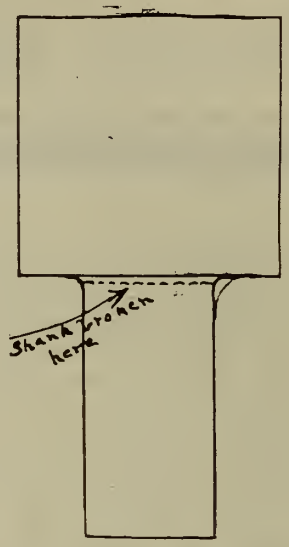
By T. H. F.

An example of a piston defect that very nearly led to serious trouble occurred in the low pressure side of a McIntosh, Seymour vertical compound engine.



PLAN AND ELEVATION OF PISTON SHOWING THE BREAK.

The piston was of the usual McIntosh, Seymour type, that is, the ring was held concentric to the piston by a number of square blocks. These blocks were made with round shanks, which fitted in holes bored in the body of the piston. One of these blocks had been broken off at the junction of the shank, and had, being free, gradually worn away the metal of both piston and junk ring, till it had made a large hole. A little further running would have resulted in the breaking of a cylinder cover, or the block, getting into the vaive openings, would have smashed up the valves.



VIEW OF DISTANCE PIECE.

Repairs were made by cutting out the metal, and fitting a patch held on by studs, riveted over into countersunk holes on the patch.

GEARS FOR RECIPROCATING ENGINES

The undoubted success which has accompanied the application of speed reduction gears to marine steam turbine installations, and the high efficiency which is obtained with these gears when they are carefully manufactured, raises the question whether it might not be an advantage to install mechanical speed reduction gearing in conjunction with reciprocating engines of the internal combustion type. There is no question as to the advisability of using them in conjunction with steam reciprocating engines, as these can be most economically built to run at a speed of about 70 revolutions per minute, which is perhaps the most economical rate of revolution for the propeller of slow-going cargo vessels having a speed of about 11 knots. But with Diesel engines, as now built, it is found impossible to run these at such low speeds, and a study of the Diesel engines built for cargo vessels would show that though the speeds vary considerably with different makers, it is always higher than that of the reciprocating steam engine, and usually between 150 and 300 r.p.m. It would appear then as if experiences are needed to determine what may be considered the most economical speed of high-powered Diesel engines, and then to build engines of this speed and install gearing having a speed reduction of two or three to one, so that the most economical propeller speed may also be employed.

The Principles Underlying the Operation Storage Battery

B. S. T. BUTLER

THERE are in use at the present time two types of batteries, the primary and the secondary. It would be advisable to make things more clear to first consider the primary battery, of which there are two groups, the closed and open circuit types. The closed circuit type will work continuously, being composed of a position pole of carbon, a negative pole of zinc, the electrolyte sulphuric acid ($H_2 SO_4$), together with bichromate of potash. In the chemical action which takes place in the cell, positively charged hydrogen (H_2) goes to the positive pole, gives up its charge to the carbon, and at the same time polarizes the positive pole, due to the high resistance of the hydrogen. The negatively charged SO_4 goes to the zinc pole and gives up its charge to the plate, at the same time dissolving the metallic zinc and forming zinc sulphate, $ZnSO_4$. The oxygen of the bichromate combines chemically with the hydrogen H_2 at the positive pole, forming water, H_2O; at the same time it depolarizes the carbon pole by reducing the resistance, thus enabling the cell to work continuously until the negative pole is consumed. This equation would be expressed: $C + Zn\ H_2 SO_4 + K_2 Cr_2 O_7 = C + ZnSO_4 + H_2O + K_2 Cr_2 O_7$. Zinc sulphate, being soluble, would be held in solution. Theoretically current sent through this cell in the opposite direction from the carbon to the zinc, would break up the zinc sulphate, $ZnSO_4$, into positively charged zinc and negatively charged SO_4. The Zn radical would go to the negative and form metallic zinc; the SO_4 would combine with the water previously formed and form H_2SO_4; this cell would give out current again and would be termed a secondary cell. The equation of this action would be expressed: $C + ZnSO_4 + K_2 Cr_2 O_7 = C + Zn + H_2 SO_4 + K_2 Cr_2 O_7$. The chemical action in the open circuit battery is the same, with the exception that the depolarizing agent acts more slowly, therefore the battery needs a longer space of time to recover itself. The voltage E.M.F. of a battery depends on the difference of potential between the two elements used; also the nature of the electrolyte. The current strength or amperes depend upon the surface area of the plates used.

Before taking up the chemical action in the secondary cell, it would be advisable to give a brief outline in connection

with the chemical terms used further on: Atomic weight, valency, and chemical equivalent and also the term molecule. For example: Henry Cavendish, in the year 1781, made the following experiments: By putting equal parts of hydrogen and oxygen into a glass receiver, from which the air had been previously exhausted, and detonating the gases by an electric spark, he found that he had created a water vapor, but still had some gas not combined. By admitting more hydrogen detonation produced the same results, giving proof that oxygen was in excess. Then by putting two parts hydrogen, one part oxygen by volume and detonating the contents he formed water vapor with no remaining gases, therefore proving their combining power or valency. In this case, hydrogen may be said to have a combining power of one and oxygen of two. For this reason it takes two atoms of hydrogen with only one of oxygen to form water.

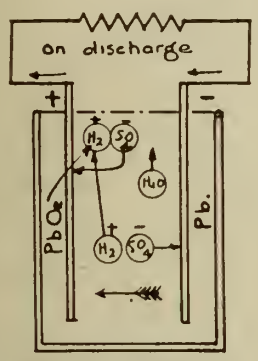


FIG. 1—ON DISCHARGE

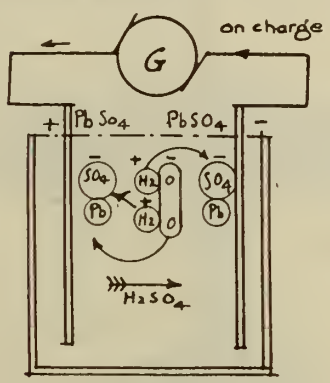

FIG 2—ON CHARGE

Combining Weight

Hydrogen being the lightest gas known is taken as the standard or starting point, and its weight is denoted by the figure one. Its chemical equivelent or combining weight is also one, for its valency, as explained above, is also one and it is for this reason termed a monad.

The atomic weight of oxygen is 15.9 as compared to hydrogen, which has a weight of unity, for equal volumes at equal temperatures and pressures. One atom of oxygen combines with two atoms of hydrogen to form water, and showing that its combining power is twice that of hydrogen. For this reason oxygen is termed a diad, its valency being two, the chemical equivalent will be $15.9 \div 2 = 7.95$.

The chemical equivalent of an element is nothing more nor less than the proportion by weight in which it combines with other elements. It also enters into the computation of the electro chemical equivalent of an element.

In writing chemical formulae correctly the positive radical should be written first, together with a number denoting the number of radicals or atoms always written to the right and slightly below the symbol. The negative elements or radicals are then written down in the same manner.

The number of the molecules found is denoted by a figure to the left hand and on the same level as the symbols.

The following examples will serve to make these terms clear: ($2H_2O$) ($2H_2SO_4$) ($2PbSO_4$). The first two examples are composed of mono-valent or monad, and di-valent or diad elements. The third one is composed of diad elements.

Having considered the primary cells and some of the more common chemical terms, we will next take up the secondary or storage cell. The term storage being objectionable and misleading, and, if used, should be used figuratively and not deliberately. To determine the action in a secondary cell, we will first give our attention to the elements used, their atomic weight, valency, chemical equivalent, and also the group to which they belong. First, hydrogen (H), atomic weight 1, valency 1, chemical equivalent 1, and in the monad group. Second, oxygen (O), atomic weight 16, nearly chemical equivalent 8, valency two in the diad group. Third, sulphur (S), atomic weight 32, valency 2, chemical equivalent 16, in the diad group. The electrolyte can now be studied. Hydrogen (H) being in the monad group. Oxygen (O), being diad, will combine two to one, thus forming a binary compound water (H_2O). Sulphur will combine with oxygen and forms sulphur dioxide (SO_2) in contact with platinum will take up one more atom of oxygen and forms SO_3. SO_3 being a binary compound, H_2O a binary compound, the two in combination give us the ternary compound, H_2SO_4, this being our electrolyte, plus H_2O, or water.

We will next take up the plates, the metallic elements in the cell, of which there are two types, the formed and the filled, their difference being mechanical more than chemical. The formed plate is made by chemical action, the filled plate is a mechanical construction, the active compound being the same on both, PbO_2. The formed plate being a chemical compound in itself can only be removed by chemical action and is thus more resistant to expansion and contraction troubles, one charge and discharge. To erect the cell we place in a glass cell one plate of lead peroxide (PbO_2), another plate of Pb or spongy lead, and so on, until cell is full; plates are covered about one inch above the top of the plated with the electrolyte (H_2SO_4), which should have a specific gravity of 1.212. The cell is now ready to give out current. We will now put our battery on discharge. See Fig. 1.

On discharge the electrolyte H_2SO_4 is broken up into oppositely charged elements. The hydrogen being positively charged goes over to the positive plate and combines with the oxygen of the litharge (PbO_2) and forms two atoms of water twice. Our negatively charged SO_4 goes to the positive plate, takes the plate of the O_2 and forms $PbSO_4$. The other part of the SO_4 goes against the current. to the negative plate and forms $PbSO_4$, lead sulphate; we now have two plates of like compounds, having no difference of potential. A battery in this condition would be termed dead. The safe working condition of a battery is reached long before this stage is reached. The specific gravity of the battery would be lowered owing to water being formed and the SO_4 going to the plate. It is by the density of the electrolyte that we determine our lowest point of discharge. Diagram No. 3 gives a normal discharge chart.

Before taking up the charge it would be well to note the relationship between electricity and chemistry during electrolysis, given quantity of electricity will liberate the same number of monad atoms irrespective of their nature, one-half this amount of the diad, one-third of the triad, one-fourth of the tetrad. Putting the battery on charge sends the current the opposite direction to the current on discharge. Assume both plates to consist of lead sulphate, $PbSO_4$, the water formed during discharge is now broken up into positively charged hydrogen and negatively charged oxygen. The positively charged hydrogen goes to the negative plate, unites with the SO_4 of the lead sulphate and forms sulphuric

ELECTRICAL SUPERINTENDENT

Applications are invited for the position of superintendent of the Electric Light and Power Department, the units of which consist of one 115 H.P. and one 75 H.P. engines, gas producer type. The successful applicant will be required to supervise the production and distribution of energy, and also the pumping of water from the deep wells, and will be required to assume duty as nearly as possible to July 1st.

Applications enclosing copies only of recent testimonials and stating salary required should be addressed to the undersigned.

FRED H. CLARKSON,
Town Clerk.

Wanted representing agents and merchants to sell and represent firm manufacturing Milling Cutters, Twist Drills, Reamers, Lathe Tools, Planer Tools, High Speed Steel and Alloy Tools, and Merchants' Tools. Good terms and discounts for selling or representing offered. Apply Lawton Bros., Woodseats Engineering Works, Sheffield, England.

For sale, complete patterns and drawings for 35 and 50 P.H. heavy duty gas engine suitable for producer gas, city gas and natural gas. These engines were designed for an American concern by an English engineer and are the type most popular in Canada. The present owners bought these at a bankrupt sale and will dispose of them at a very low figure. Write us for drawings and details.

(Continued from page 263.)

acid (H_2SO_4), leaving spongy lead at the negative plate. The negatively charged oxygen flowing against the current goes to the positive plate, unites with the lead Pb of the lead sulphate $PbSO_4$ plate and forms lead peroxide (Pb_2). The SO_4 part of the positive plate united with the rest of the hydrogen liberated when the current broke up the water into H_2 and O, forming more sulphuric acid H_2SO_4 and leaves a plate of PbO_2, lead peroxide. The cell now has a difference of potential of about 2.2. This action would be attended with a rise in gravity of the electrolyte and ready to furnish current. Also a rise in temperature, due to H_2SO_4 being formed. Fig. 2 gives the chemical action on charge.

Western Association of Mechanical and Electrical Engineers

Edmonton District Loop No. 5

This Association would be pleased to receive correspondence from any engineers who would like to associate with us with a view of getting better conditions for the craft in general. We would also be pleased to have communications from any other society or societies of engineers who are endeavoring to secure these conditions. Address all communications to

The Secretary,
Western Association of Mechanical and Electrical Engineers.
P.O. Box 991, Edmonton, Alberta, Canada

THE LONG Patent Steam Trap

Has Only One Moveable Part

The Long Patent Steam Trap is advanced in construction. Has positive advantages over all other traps, and is protected by patent rights.

The valve is actuated by the expanding and contracting of a tube, a motion that is positive and of sufficient force to close the valve against a pressure of 200 pounds. The movement is due to the expansion and contraction of different metals.

Works against 1 and 200 pounds of pressure—no possibility of freezing. Has two outlets so it can be installed in any position. Applied to drain steam lines, mains, Jacket kettles and separators and can be adopted in drying room systems.

FULL DETAILS UPON REQUEST. YOU'LL SAVE MONEY.

TRADE GOSSIP

Electric Light for Barrington Passage: A company was incorporated at the recent session of the Nova Scotia Legislature for the purpose of developing power from the Barrington River to serve the villages of Barrington, Barrington Passage and Woods Harbor. The Naval Department has a large wireless station at Barrington Passage, which played an important part in the recent naval activities in this neighborhood.

Niagara Falls Gas Plant.—The Niagara Falls Gas & Electric Light Company are to erect a modern gas plant to cost $200,000 on a four-acre site at 27th Street and Buffalo Avenue. The plant will be completed and ready for operation by January 1st, 1920.

Oshawa. — Oshawa endorsed the proposition of the Ontario Steel Products Co. of Canada, by voting them a fixed assessment for ten years, by a majority of 596 votes. This concern will erect modern factory buildings on the Rider property in the north-eastern section of the town, for the manufacture of automobiles, springs and axles, of which the huge McLaughlin and Chevrolet plants will take almost the entire output. 150 men will be employed.

Agreement is Arrived At.—The Robb Engineering Works, of Amherst, N.S., have arrived at an agreement with their employees, under which the men get an eight-hour day, and a forty-eight-hour week. Time and a half for overtime, and double time for Sunday will be paid; also for holidays. These arrangements come into force after 30th August. From June 1st till Aug. 30th, a fifty-five-hour week will be worked, the pay to be the same as for the fifty-nine-hour week, at present in force.

New Mill Makes Progress: The development of water power, erection of buildings and installation of machinery for the new mill of the Kipawa Fibre Co. at Lumsden's Mills is proceeding rapidly. A dam has been built at Gordon Creek about 200 feet above the Ottawa River level, and an ultimate power development of 20,000 H. P. is expected here. Four thirty-ton digesters are in position, and about one-third of the buildings have been erected.

New Fire Alarm System: The town of Sarnia is about to install a new and up-to-date fire alarm system. The Northern Electric Company is carrying out the contract. The switchboard at the central fire hall will handle four circuits at present and provision for extension is made. Storage batteries will be employed, charged through a motor generator operating on hydro-electric current. An automatic indicator will be installed, which will show the number of the box from which the alarm is rung in. The outside equipment will also be added to where needed, and the whole system put on a thoroughly modern and efficient basis.

LLOYD HARRIS

Chairman of the Canadian Trade Mission in London, on his return from Europe last week, gave at the Annual Meeting of the C.M.A. an immensely interesting address with valuable, practical pointers closely detailed on

THE RIGHT METHODS FOR SECURING FOREIGN TRADE FOR CANADIAN FACTORIES

The only full stenographic report published of this splendid address appears in the June 14th issue of

THE FINANCIAL POST

Send for your copy of THE POST to-day and secure with the Lloyd Harris address THE POST'S usual splendid service of information of big value in the development of Canadian business. Here are a few of the contents of THE POST for June 14th:

Prospects for Steel Orders Are Increasing.
Rallying Union Forces to Support of White Budget.
Bolshevism at Last Arousing Ottawa.
Toronto Rails Faces Serious Strike Problem.
Incorporation of New Oil Companies Breaks Record
May Building Permits Show Good Increase.
Saguenay Pulp Has Bond Issue of $5,500,000.
Maritimes Charge Discrimination.
Bond Market Develops More Life and Action.

These are just a few jottings from THE POST contents list of June 14th, and the contents list gives only a few of the leading articles. You will find far more of interest, and perhaps of actual cash value to your business in THE POST'S big service of factful news and shrewd comment on commercial affairs.

When you "get down to business" you want the plain facts —all of them—without frills—and quickly. You get them like that in THE POST. THE FINANCIAL POST will keep you informed on Canadian business matters in a way unrivalled by any other publication. Send for a subscription to-day. The price is $3.00 per year, and you have only to fill in this form:

The MacLean Publishing Co.,
143-153 University Ave., Toronto.

Send me THE FINANCIAL POST every week till further ordered. I will pay subscription price, $3.00 per year, on receipt of bill, or you may draw on me for this.

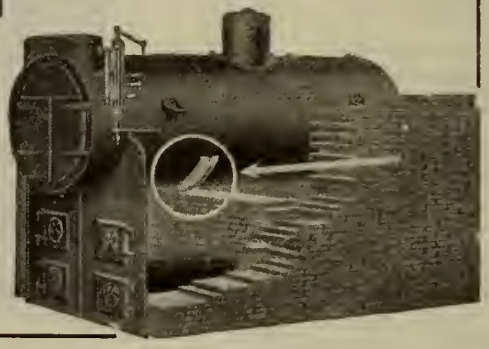
HINTS TO BUYERS

NATIONAL Boiler Girth Seam Protector

Protection means longer life and greater efficiency

If your Boiler is not Fire-cracked it eventually will be. Prevent this by putting on a National Boiler Protector. You will save cost in repairs and prolong life of the boiler. All new boilers should be protected. If your girth seam is giving you trouble at the present time, have the seam caulked up, attach one of these protectors and the seam will remain absolutely dry thereafter.



Guaranteed for one year. We make protectors for patches and all styles of boilers. For full particulars, write—

Why Did We Let Trotzky Go?

THERE was a time when Canada had it in her power to end the war. In the early days of the Russian Revolution a bushy-haired German was taken off a boat at Halifax and interned at Amherst, N.S. He pretended to be a Russian but was known to be in German pay—on his way to push the revolution—British and American Intelligence Officers so informed our authorities. But pressure was brought to bear and the man was finally released. He got to Europe and became the most sinister figure among the Bolsheviki. Largely as a result of his work, Russia dropped out of the war and Germany was able to fight on for eighteen months. That man was Leon Trotzky. His real name was Braunstein.

Why was Trotzky allowed to leave Canada?

Colonel MacLean discusses this question in the June issue of MACLEAN'S MAGAZINE. He tells the story of Trotzky's activities, of his arrest and subsequent release in full detail, tracing the threads of a strange intrigue from Germany to Washington, and Washington to Ottawa. It is a gripping story, the most important inside story of the war.

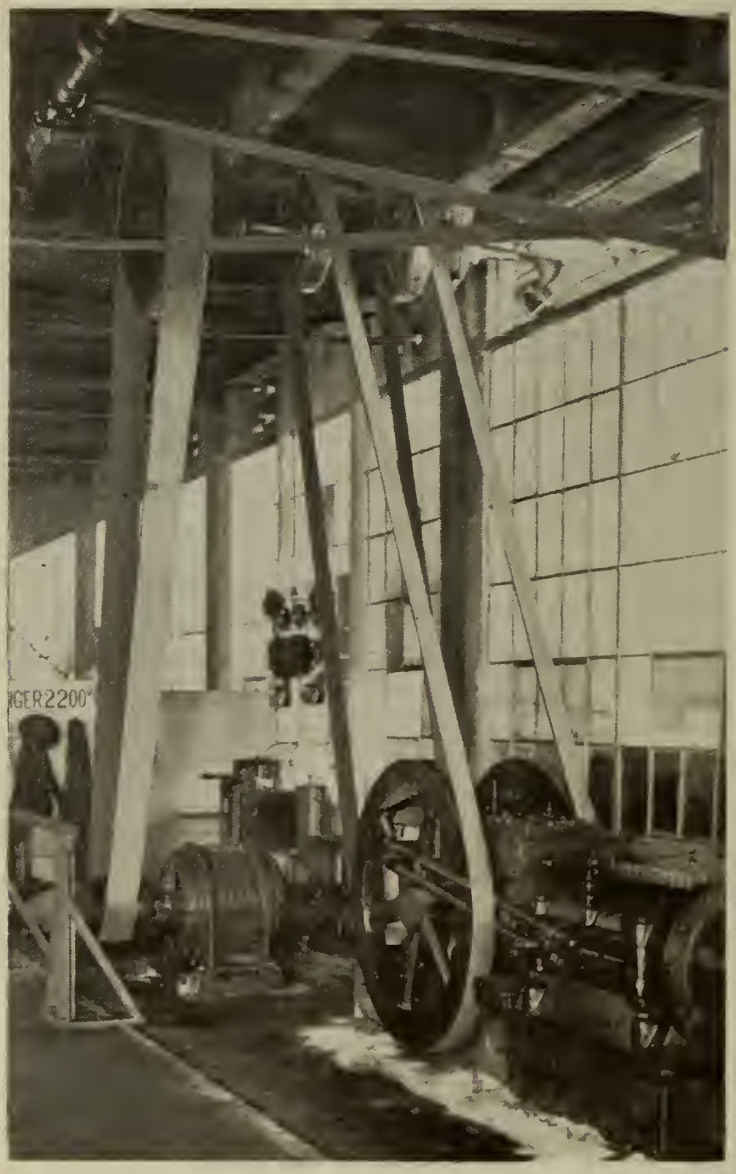
ON SALE AT ALL NEWSDEALERS



Trussed Concrete Steel Co., Limited Walkerville, Ont.

FOR INSTANCE---

The Trussed Concrete Steel Co., Limited, of Walkerville, Ontario, is one of the foremost reinforced concrete concerns in Canada, as well as the largest Canadian manufacturers of steel sash and steel casement windows. Their opinion of Goodyear Extra Power Belting is pithily expressed in this letter from Mr. S. Farrell, purchasing agent:

"We have been users of different types of belts for quite some time, but we have no belt which will stand wear as long as the Goodyear Extra Power Belting, which we purchased from you some time ago. The photograph shows your "Extra Power" belt in use on an air compressor. It has been in use on same for some time and is still as good as new, while other belts previously used lasted only two weeks. We are gradually replacing all our belts with Extra Power."

GOODYEAR
MADE IN CANADA

Power Costs Money---Conserve It

Goodyear Extra Power Belting Costs You Less Because of Longer Service---And Saves Enough Power to Pay for Itself

Industry wastes a great sum of money through inefficient transmission of power.

Belts slip—pulleys are out of alignment—bearings worn—belts too heavy or too light. And yet superintendents and managers wonder why production slows up—why costs mount.

Today thousands of Candian industrials have reduced their power-waste measurably through the correct application by Goodyear men of Goodyear Extra Power Belts to their drives.

Goodyear Extra Power Belts have increased power transmission in many cases to a remarkable degree.

They have provided steady, uninterrupted operation of vital machinery.

They have given long, low-cost service.

Letters on our files vouch in cold figures and warm praise for the results obtained from Goodyear Extra Power Belts.

A Goodyear man will call on you at any time you say—without obligation to you. He will record the size of pulleys, horse-power transmitted, speed, length of drive, conditions of work. And when our recommendation comes to you, it will bear the stamp of engineering ability. Phone, write or wire the nearest branch.

Carling Turbo Blowers

For burning the lowest grades of coal successfully, getting all the heat value from the fuel. For positive draft with Automatic Control and steady steam pressure. For obtaining the ultimate capacity from the boiler.

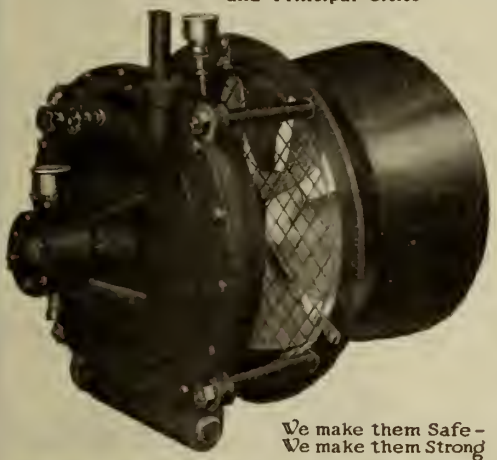
Carling Blowers are low in first cost, easy to install and make a quick return on the investment. We will be pleased to show you why it pays to use Carling products.

Write to-day. Try at our expense.

CARLING TURBINE BLOWER COMPANY

Engineers and Manufacturers WORCESTER, MASS

Canadian Representatives: Green's Economizer Limited, Toronto and Principal Cities



Turbine Undergrate Blowers, Centrifugal Blowers and Exhausters, Small Power Turbines, Damper Regulators and Grates

We make them Safe—
We make them Strong

GALT SPRINKLER STOKERS

Effect a saving in coal from 10% to 20%. Effect a saving in labor from 25% to 50%.

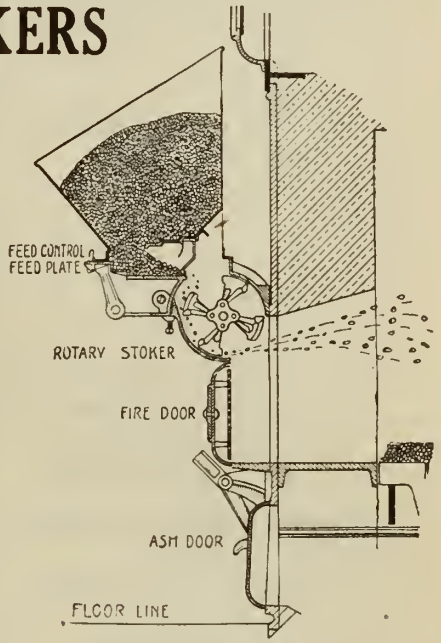
Give 170% boiler capacity on natural draft with a fire three inches thick.

Operate with natural, forced, induced or any kind of draft.

Burn any kind of fuel, anthracite, bituminous or lignite.

The Galt Sprinkler Stoker mechanically feeds and perfectly spreads the fuel over the entire length and width of your present grates with the fire doors closed.

It has been very successful in the past and recent installations have given better results than ever.



May we send full particulars?

The Galt Foundry Co.

GALT, ONT.

HOMESTEAD Quarter-Turn Valves

Straightway, Unobstructed Flow!

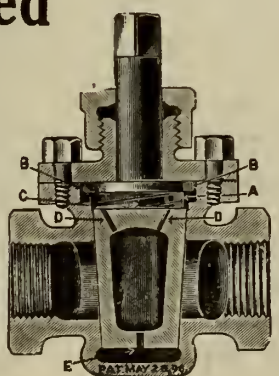
No valve but a Homestead will give straightway, unobstructed flow.

The full pipe area is another exclusive Homestead feature.

Just one-quarter turn opens and closes a Homestead Valve—still another Homestead exclusive feature.

That's why Homestead has replaced globes and gates in hundreds of plants.

They are used for air, steam, water, oil, acids, etc.



Homestead Valves are made in Straightway, Threeway and Fourway patterns for all conditions of service.

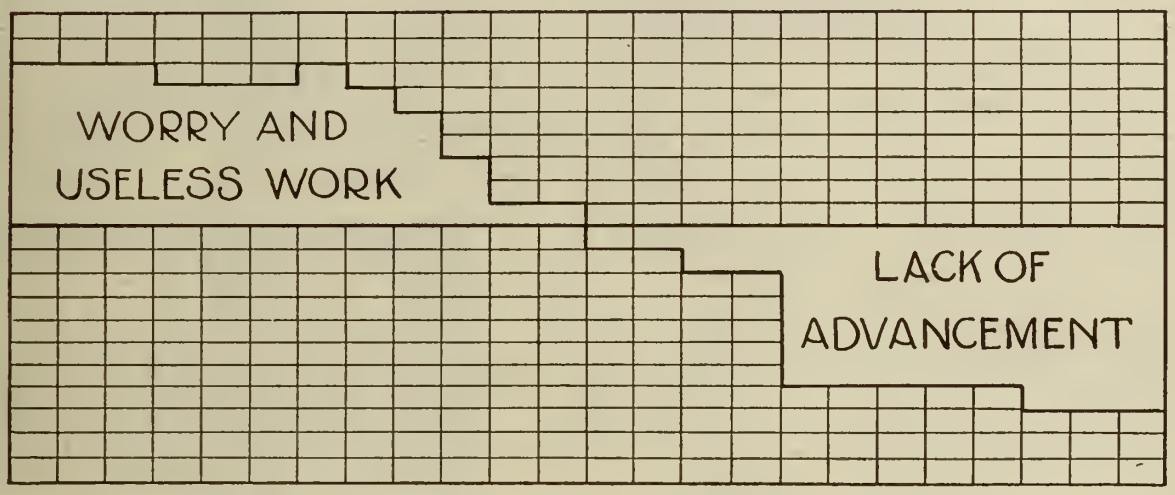
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

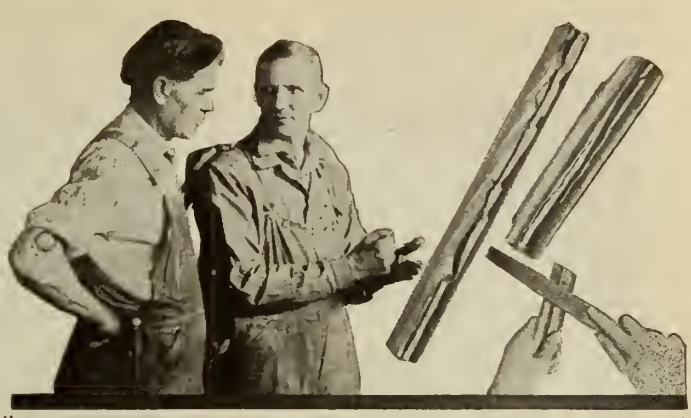
Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID,
Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D.,
Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.



We Jacked 37 Tons on These Jeffrey Roller Bushings Before They Distorted A Bit.

"You see the Jeffrey people give the Double Bushings of the Jeffrey Improved Carrier a special heat treatment which makes a glass-hard finish that is practically immune to wear. But we wanted to be sure that these bushings had the right toughness and resilience to stand the 'gaff.'

"There's no proof so convincing as a practical test. When these bushings stood up without distortion with the gauge reading 37 tons, we were satisfied. Moreover, the ragged fracture shows that the initial toughness is preserved and increased.

"The second test was just as interesting as the first. They tried to gnaw through the outer walls with a sharp file—but nothing doing. It's glass-hard, all right."

The Jeffrey Co. are putting out **Bulletin No. 210-4**, which describes the Carrier completely and tells of the practical test they made before they were satisfied with the Reliability and Dependability of this New Jeffrey Carrier. You'll never regret investing a stamp to write for it.

"Copes Specifications" for Boiler Feed Regulation are Now in Print and Ready for Distribution

As stated in this pamphlet of specifications, the Copes System briefly comprises:

(1) Continuous feed in proportion to the load.
(2) Heat storage because of the variable water level principle.
(3) Reduction of furnace temperature fluctuation on sudden load changes.
(4) Constant unchanging and reliable mechanical performance.

The Copes System of Boiler Feed Regulation combines scientific control of the boiler feed with permanent mechanical performance. The feeding is continuous in proportion to the load and is accomplished without the use of floats, springs, diaphragms, boiling liquids, pilot or needle valves, or other unreliable or hidden parts.

The specifications pamphlet discusses the following points:

Principle and Operation—Tells how the Copes Regulator operates—why it is so certain and dependable.

Heat Storage—Shows what happens when the load is constant, increasing and decreasing.

Reduction of Furnace Temperature Fluctuations on Sudden Load Changes—An important feature that should be carefully studied by every boiler operator.

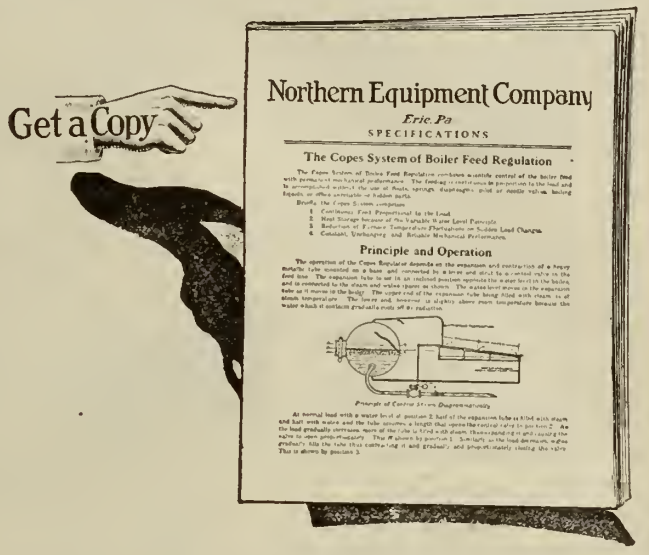
Service Performance—A chart shows changes in water level, feed valve opening, steam output, and water input under ordinary operating conditions. The chart proves that Copes Regulators do their work SCIENTIFICALLY.

Constant Characteristics—This portion explains why the Copes Regulator regulates with unvarying accuracy, year in and year out. It depends for its operation on two unchanging and natural forces—expansions and gravity. No parts to deteriorate, to replace, or to adjust frequently.

Flow Characteristics—Showing that the flow through a Copes Regulator is exactly proportional to the lift of the valve, the flow characteristic being a straight line.

Thermostat—Illustrating the simplicity of construction of this important part of the regulator.

Control Valve—A very interesting description with illustrations showing why practically 100% of the friction of the old-fashioned sliding rod has been eliminated.



The remaining portion of the specifications pamphlet is devoted to:

STANDARD DIMENSIONS AND DRILLING
COPES STEAM PUMP GOVERNOR
THE COMPANY
ORGANIZATION
SERVICE

Fill in the return coupon below, and we will send the Specifications Pamphlet, Catalog "A" or both if desired, and any additional information you wish.

It should be borne in mind that the Copes Regulator is now standard in all of the power plants in the country and is invariably specified by efficiency engineers, who have given feed water regulation careful study.

Wanted—

Engineers to contribute to Power House

THIS is a practical paper for practical engineers. It is an educational medium and out to help its readers. It is a technical school and a social meeting place combined. It is first, last and all the time an engineer's paper.

If you should meet two or three or a dozen of your brother engineers you would swap ideas—you'd tell of some idea you had worked out in your plant. Others would describe some pet schemes they had devised. And so you would be mutually benefited.

Why not make Power House your monthly meeting place? Why not describe in this paper some kink or scheme you have worked out and found successful? We will pay you for it and you, in turn, will be multiplying the usefulness of your idea five thousand fold!

Never mind polishing up your letters—just give us the idea; that's the main thing. Never mind how crude your pencil sketch may be. We have draughtsmen who will finish up your drawings so they may be reproduced.
Try this idea a time or two and see how much satisfaction you'll get out of it. Start the ball a-rolling and thus help other engineers, yourself and your paper.

POWER HOUSE, 143-153 University Avenue, Toronto

A Double Service in One Instrument

Both the temperature and pressure of the steam is shown on this *Tycos* Thermo Steam Gauge. Just the thing for saturated steam. A uniform efficiency of boiler maintenance is the result. Graduated for either high or low pressure. Range of low pressure approximately 200° to 350° Fahrenheit 100 lbs. pressure. Range of high pressure about 200° to 420° Fahrenheit 300 lbs. pressure. Made in angle form or straight connections.

We know you'll be benefited by reading our catalogue. Choose the one you are most interested in from the list below.

Tycos Angle and Straight Stem Thermometers, Automatic Temperature Regulators, Mercury, Vacuum and Absolute Pressure Gauges, Engraved Stem Thermometers, Hydrometers, Hygrometers, Thermo-Electric and Radiation Pyrometers.

Dependable "BOND" Transmission

FIG. 1—"Bond" Patent Universal Drop Hangers, Ring Oiling Ball and Socket, Universal Adjustment.

FIG. 51—"Bond" Double Flange Solid Set Collar.

FIG. 19—"Bond" Rigid Ring Oiling Pillow Block. A well constructed bearing babbitted and reamed and self oiling.

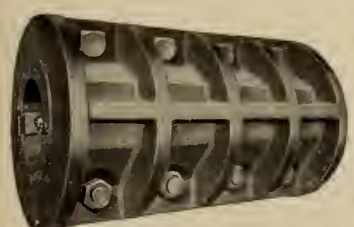

FIG. 45—"Bond" Clamp Coupling.

B
D-S
BOND DOUBLE-SURE QUALITY

IT is the transmission that eliminates power leaks. Power engineers in the United States and foreign countries appreciate the great strength and durability of the Bond Hangers, etc. They deliver the power where the manufacturer wants it. They run true, year in and year out, with little friction. They are economical to install.

Bond Shaft Hangers have steadily gained an international reputation. Observe their construction. They are doubly braced, distributing the strain evenly. It is this strength that makes them better than other types. The yoke is removable, which enables the shaft to be placed in position quickly. Adjustments can be made, both vertical and lateral, for absolute alignment of the shaft.

During the war period we furnished Transmission to Government Army and Navy departments, for contractors working on government contracts, and for cantonments in France.

Industries that could not afford to check production for a moment, during the war period, assured maximum production by using Bond Transmission.

We would like to send to you our "Power Transmitting Machinery" booklet. Our large manufacturing facilities, combined with our many years of foreign trade experience, enables us to place at your command a wealth of valuable information which will help you, as it has many others, to solve power problems.

Write us direct, or through your regular dealer.

Bond Engineering Works

LIMITED

Harbor Industrial District Toronto, Canada

The "Bond" Patent "Spiro" Coupling, has 50% more gripping power than any other compression coupling on the market, due to patented spiral slot.

FIG. 45—"Bond" Clamp Coupling.

Dependable "BOND" Transmission

B
D-S
BOND DOUBLE-SURE QUALITY

IT is the transmission that eliminates power leaks. Power engineers in the United States and foreign countries appreciate the great strength and durability of the Bond Hangers, etc. They deliver the power where the manufacturer wants it. They run true, year in and year out, with little friction. They are economical to install.

Bond Shaft Hangers have steadily gained an international reputation. Observe their construction. They are doubly braced, distributing the strain evenly. It is this strength that makes them better than other types. The yoke is removable, which enables the shaft to be placed in position quickly. Adjustments can be made, both vertical and lateral, for absolute alignment of the shaft.

During the war period we furnished Transmission to Government Army and Navy departments, for contractors working on government contracts, and for cantonments in France.

Industries that could not afford to check production for a moment, during the war period, assured maximum production by using Bond Transmission.

We would like to send to you our "Power Transmitting Machinery" booklet. Our large manufacturing facilities, combined with our many years of foreign trade experience, enables us to place at your command a wealth of valuable information which will help you, as it has many others, to solve power problems.

Write us direct, or through your regular dealer.

Why Dominion Friction Surface belting keeps employees satisfied

There are few manufacturers who haven't discovered that satisfied employees are an absolute necessity to low cost of production.

But poor equipment will not keep employees contented — it will not permit maximum production — it increases upkeep cost — it creates needless waste of time for operators and machines while making repairs.

Dominion Friction Surface Belting, in eliminating these conditions, does much to keep employees satisfied, for it enables operators to turn out maximum production at low cost — does away with most transmission troubles and saves power by taking a grip on pulleys that practically prevents all slipping.

Our Belting Experts are ready to show you how this "plus service" belting will keep your employees satisfied, just as they have for many other manufacturers. Phone wire or write to our nearest service branch—there is no obligation.

TALBOT

Contra-Flow Steam Boilers

(Equipped with Crude Oil Burners)

SAVE ONE-SEVENTH THE SPACE OF THE ORDINARY BOILER.

NO BRICKWORK IS NECESSARY.

COST OF OPERATION LOWER THAN ANY KNOWN POWER PRODUCER.

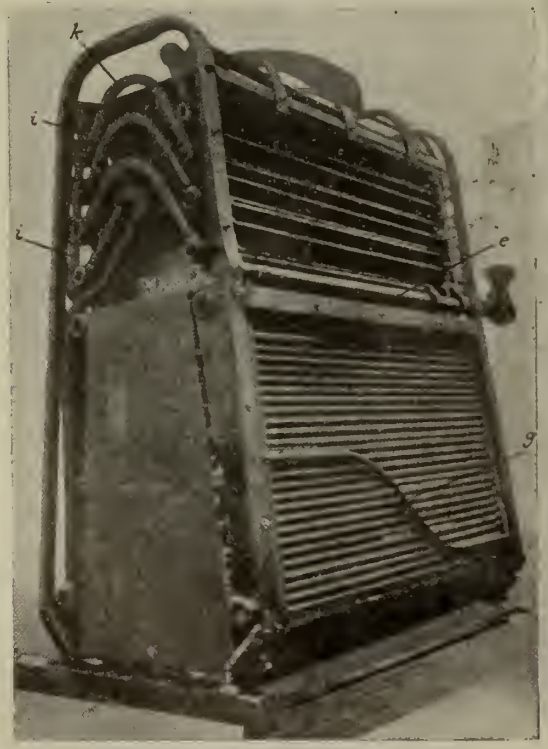
Water enters near the stack and leaves in the form of steam near the furnace.

No water drum. Circulation is through water tubes and is forced at a high velocity by means of a pump.

No Steam Drum

By preventing gravity circulation the steam is drawn directly from the lower tubes.

The boiler is internally fired, and hence self-contained. Feed water and fuel burners are automatically controlled to adjust the boiler to widely varying demands for steam.



Head of Boiler Casing Removed

Tubes easily replaced under reduced steam pressure. Write for Catalogue B.

In Canada's Biggest Industries

Where absolute certainty must be counted upon at all times, no chance can be taken with equipment.

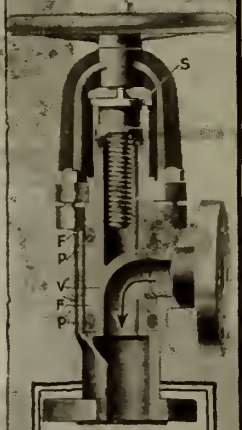
In the big industries, especially must every detail be efficient—the blow-off valve as well as the boilers, pumps and engines.

So, when the big Canadian corporations such as the following instal Yarway (formerly the Simplex) "Seatless" Blow-Off Valves, their choice becomes an endorsement of the very highest character.

Canadian Explosives Co., Ltd., have 11.
Dominion Iron & Steel Co., Ltd., have 20.
Canadian Pacific Railway Co., have 24.
Bathurst Lbr. Co. have 8.
Montreal L., H. & P. Co., have 24.
International Eng. Wks., Ltd., have 13.

And there are many others. With the Yarway (formerly the Simplex) "Seatless" Blow-Off Valve there can be no sudden opening and closing to injure tubes; the operation is simple, certain and safe; the valve does not leak: it requires but little attention as there are no weak places such as seats or discs to cut and scar; even the packing lasts for years. You can verify each of these claims by testing the Yarway on one of your boilers for 60 days. Return it if not satisfactory.

Write to-day, stating size of line, and whether screwed or flanged, angle or straight-way.



Operation: In closing valve shoulder "S" on plunger "V" engages the lose follower gland "F," compressing packing "P" above and below the port, making an absolutely tight valve.

TORONTO JULY 5, 1919

Oversold Output Is Advertising Impetus

AMONG the factors which make advertising such a dominant force in American business is the faith of the largest investors in the printed word.

It wasn't so long ago—as a matter of fact has the time really passed?—that a manufacturer curtailed his advertising because his factory was oversold. The old cry, "Nothing to advertise; I'm flooded with orders," ruled.

Fortunately for the manufacturer, this view has given way to sound merchandising. The advertiser to-day sees the value and necessity of intrenching himself in the market he has won, even though the counter attack of his competitor seems far off, even improbable.

Back in the days when the world was engaged in position warfare it was a principle that a portion of captured line must be **consolidated** without delay. The whole idea was this—a section of the enemy's line had been captured, but that enemy's dominant purpose was to reform his forces and counter attack. Sometimes the position was lost and taken a dozen times.

This necessity of consolidation, of digging in and preparing for the counter thrust, exists in business. And the more important the position held, the more tempting is the counter attack desire.

The Goodyear Tire & Rubber Company recently threw a bulwark of newspaper pages between its business and competition. This concern advertised that in spite of an output increased to an average of 24,536 finished tires a day, it had been impossible to meet existing demand for its product.

The consumer is told that the Goodyear Company regrets its inability to serve all of its customers, despite its increased production.

The dealer is not neglected. The consumer is asked to overlook any shortage in the dealer's stock because of the impossibility of keeping that stock complete. This is another link in a remarkably fine consolidation.

All this goes to show that this keen advertiser knows that it does pay to advertise aggressively even though the factory output is sold out a long way ahead.—Printers' Ink.

Fire-Brick Wall Set Up With High Temperature Cement No. 31

Fortifying Furnace Settings Against Heat Attacks

IN every furnace setting there are hundreds of weak spots where adjacent brick sides and their edges meet.

It is here that heat inflicts its first damage—makes repeated attacks on the clay mortar, which crumbles, drops from place, and exposes the entire setting to rapid disintegration. This is the "why" of a short-lived and leaky setting.

The setting can be fortified against early failure by employing

Johns-Manville Heat Treatment

as a bond between bricks. They provide a cushion for brick expansion and contraction. They vitrify and retain their properties under high heats.

The entire fire-brick setting face should be coated with Johns-Manville High Temperature Cement, which, on vitrifying, presents an homogeneous, finished coating, which is unaffected by setting contraction and expansion, and proof against the adherence of clinkers. By filling in surface irregularities of the masonry, which it does, it prevents local hot spots and the consequent spawling or cracking of bricks. Ask our nearest branch to furnish interesting details.

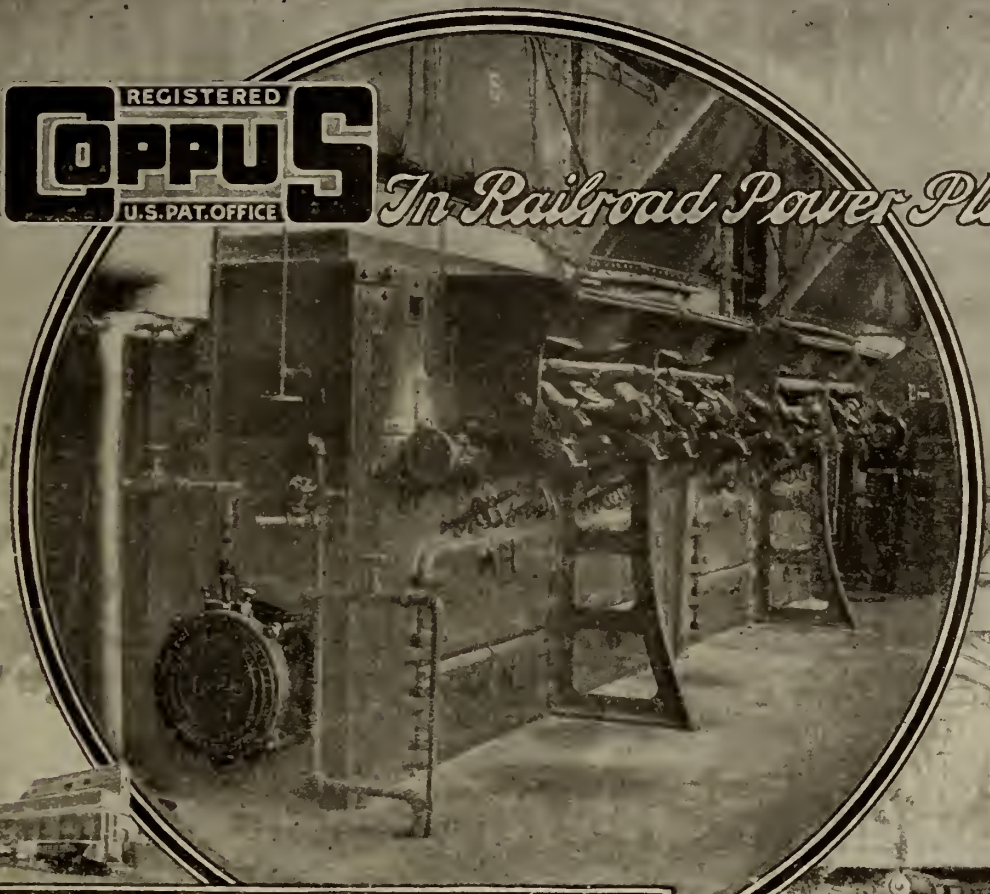
"SPARE THE ROD"

REGISTERED COPPUS U.S.PAT.OFFICE

In Railroad Power Plants



Railroads are sticklers for efficiency. Equipment approved by them must produce results—save money—earn dividends. The fact that the Central Railroad of New Jersey operates twenty-six COPPUS Turbo Blowers in their great shops at Jersey City —proves that these blowers pay.

Every one of this big battery of blowers—one of which is shown above—has cut coal costs—reduced labor charges—and saved dollars. In this power plant—as in thousands of others—COPPUS Blowers keep up steady steam pressure—prevent clinkering—meet peak loads quickly—and burn cheap fuel.

COPPUS Blowers pay a profit to the Central Railroad of New Jersey. **They can do as much for you.** Why not put them on the job? Catalog H-10 will show you how "COPPUS Equipment can save you money."

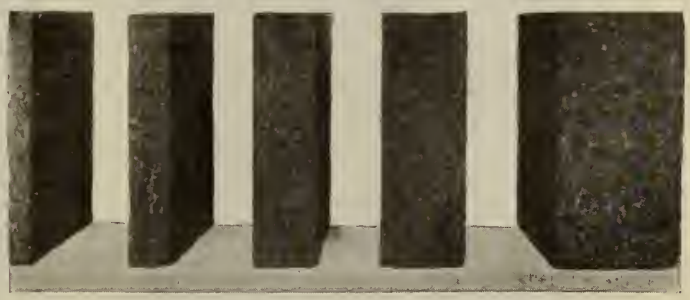
Quadruple Inspection Means Uniform Quality

Uniform high quality, which is so necessary in cold storage insulation, does not just happen. It results only from the careful selection of raw materials, scientific manufacturing methods and the rigid inspection of the finished product. The uniform high quality of



Nonpareil Corkboard — 1, 2, 3, 4 and 6 inches thick, sawed through the middle. Notice the uniform structure in all thicknesses.

NONPAREIL CORKBOARD INSULATION
For All Cold Storage Rooms

is obtained by using only the best cork waste produced, the larger part of which comes from our own plants in America and abroad. All of the granulated cork is carefully screened to take out the fine particles, dust and other foreign matter, which decrease the strength of the corkboard. The baking is done in scientifically constructed ovens, thus insuring uniform and thorough baking in all thicknesses. This is a most important operation, since corkboard that is not properly baked will not stand up in service. The edges, ends and sides of every sheet are trimmed and sanded by machinery, making them uniform in size. Finally, each finished board is inspected four times before it leaves the factory, thereby assuring the purchaser that his Nonpareil Corkboard will have the same uniform high quality that has earned for this material the title of "The World's Standard Cold Storage Insulation."

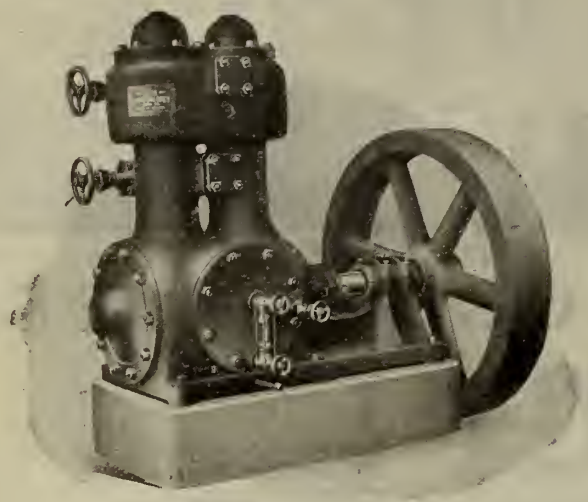
Complete stocks of Nonpareil Corkboard constantly carried in our warehouses at Toronto and Montreal enable us to make prompt shipments to any part of the Dominion. Literature and samples will be cheerfully sent on request.

Armstrong Cork & Insulation Co., Limited, 504 McGILL BUILDING, MONTREAL, QUE.

Also manufacturers of Nonpareil Cork Covering for cold pipes and Nonpareil High Pressure Covering for all steam lines

MECHANICAL REFRIGERATION

SAVES MONEY :-: HELPS BUSINESS



"We wish to express our satisfaction with your plant, which in the past several years has saved not only money and labor, but proved a business asset as well," writes one of our customers.

Here is the whole story in a few words. No addition to your business offers more certain returns on the investment than MECHANICAL REFRIGERATION.

If your business is lagging, it can be improved by the use of MECHANICAL REFRIGERATION. If your business is good, it can be made better by installing a YORK REFRIGERATING PLANT.

Write to-day for information and prices.

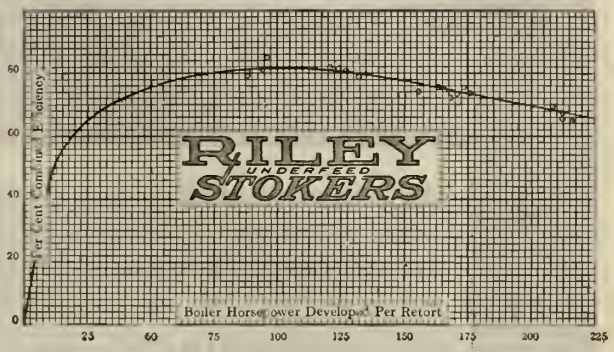
High Efficiency



THE high efficiency with which the Riley Stoker operates is shown by the above curve which is plotted from a series of tests conducted on a sixteen-retort stoker installed under a 1373 H.P. boiler at the Essex station of the Public Service Electric Company, of Newark, N.J. The continuous high efficiency and large overload capacity are due to two very important features:

1. **The moving grates** which keep the fuel bed open, porous and free from clinkers.

2. The continuous automatic ash discharge which removes the refuse as fast as formed.

Our catalog HR-7 explains in detail how the Riley Stoker with its live-grate surface boosts efficiency and increases capacity.

For information on the Murphy Automatic Furnace for smaller boilers, see June 20th advertisement, or send for Murphy catalog HM-7.

POWER HOUSE

Established 1907 Published Semi-monthly

The Brantford Power Plant of the Massey Harris Co.

An Installation Recently Overhauled and Brought to a High State of Efficiency. New Steam Piping Has Been Installed Throughout

By W. F. SUTHERLAND

BRANTFORD'S industries have gained for her the enviable reputation of being one of Canada's foremost manufacturing centres, and the many factories require considerable power for their operation. Much of this is at present obtained from the Hydro-Electric system; some is developed locally through the utilization of the Grand River, and the remainder is generated in isolated steam plants.

The power plant of the Massey-Harris Co. is one of the larger of these and contains a number of features of interest to the operating engineer.

The shavings and other mill waste from the carpenter and woodworking shops forms a major portion of the fuel used, and the boiler-room for this reason is of interest to those accustomed to the use of coal for fuel. The three boilers at the end of the battery are fitted with shaving spouts and the shavings are fed directly onto the grate bars from the exhaust system. The remaining boilers, or such of them as are used, are fed by air-blast through cyclones.

During the night when the woodworking shops are shut down, coal is used, when the excess mill waste and shavings accumulated throughout the day is used up.

Six boilers are installed, five of them 72 in. by 16 ft., of John Inglis make, and one 74 in. by 14 ft. boiler of Goldie and McCulloch make. These boilers are connected by a common steel breeching to a radial brick stack of 6 ft. opening at the top, and 150 ft. high. The breeching, where it enters the stack, measures 4 ft. wide by 7 ft. high.

Plastic cement is used on the boilers for the elimination of air filtration.

The Engine Room

The plant is supplied with the major portion of the power required by means of a jackshaft running through the engine-room and belted to the 300 h.p. cross-compound Wheelock engine there installed. This main drive belt is a 30-in. Beardmore and has been in constant service for over 20 years.

The Wheelock engine is run condensing in the summer and the exhaust steam is used throughout the colder months for heating purposes. A Goldie and McCulloch jet condenser is installed.

An auxiliary lighting set is installed for use when needed. This unit consists of a 50 kw., 110 volt d.c. generator direct connected to a McEwen high speed engine of Waterous manufacture.

WHEELOCK ENGINE—THE BELT SHOWN HAS BEEN IN USE FOR OVER 20 YEARS.

During the overhauling of the plant recently completed, a Bury compressor, made by the Bury Compressor Co., Erie, Pa., was installed, taking the place of an older machine, which had outlived its usefulness. The new machine is of the two-stage intercooler type and supplies air for shop purposes and for the sand-blasting department.

The smithy is provided with its own engine, a 14 in. by 34 in. Wheelock engine of 125 h.p. This engine in addition to the smithy requirements also drives a Jones and Moore 25 kw. d.c. generator used for charging storage batteries, which operate the time clocks, fire alarm system and the automatic telephone exchange.

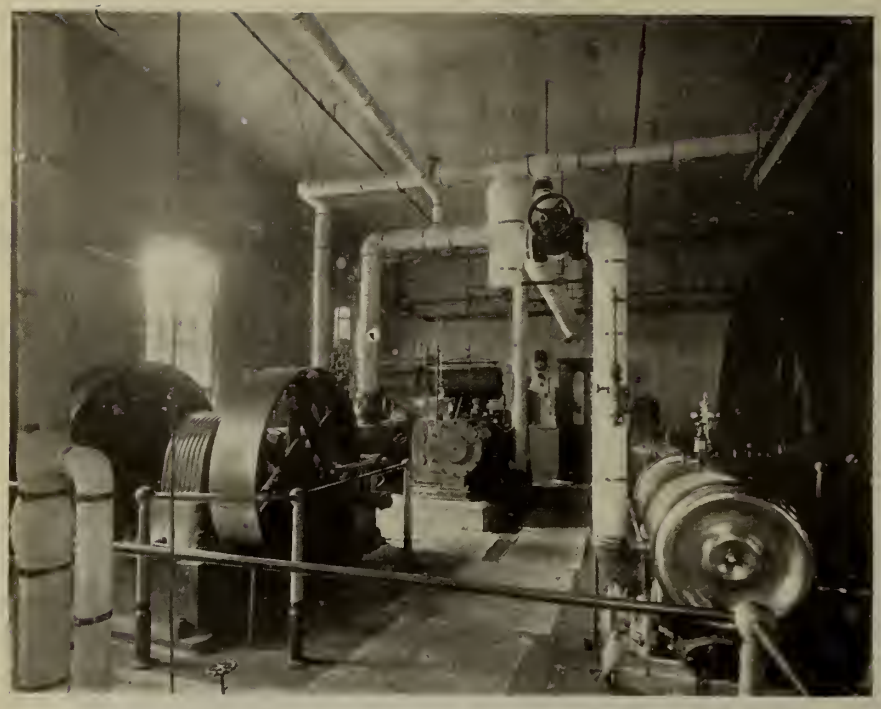
The smithy also has its own compressor, a 22 x 14 in. Bury machine with an 8 in. suction and 5 in. discharge.

The engine and compressor in this department are fed from the boiler-room through a steam header from the main engine-room.

Steam Headers

Together with other alterations which have been completed, the steam piping has been made, which greatly added to the efficiency of the plant. Purdy Mansell, of Toronto, had charge of this work and also of the alterations to the heating system, which occurred at the same time. The buildings are now heated with exhaust steam from the various engines and compressors, approximately 17,000 sq. ft. of 1¼ in. pipe radiation having been installed in the various mechanical departments.

The main steam header is 10 in. and the risers from the boilers enter it from the bottom, each riser being drained at the header and the drips lead back to a drip header, from which any condensation is removed by a trap.



ENGINE ROOM SHOWING COMPRESSOR AND McEWEN ENGINE.

From the main header separate lines are carried to the underwriters' fire pump, the engine-room and to the engine in the smithy. The main to the fire pump is of 5 in. pipe, that to the engine-room 8 in., and that to the smithy 4 in.

A four-inch exhaust line is carried through the smithy and forge shops for heating purposes.

The exhaust from the engines and auxiliaries is arranged in such a manner that it can be passed through the feed-water heater on its way to the heating mains, or the heater can be by-passed for cleaning at any time desired.

Webster traps are fitted throughout and a Tod-Atwood vacuum pump removes all condensate from the heating mains, returning it to the heater. This pump is 4 by 4 in. and is capable of handling all condensate from 37,000 ft. of 1¼ in. pipe, besides radiators.

A live steam line, 4 in. diameter, is also carried to the blast engine for the cupola in the foundry.

Lagging

All steam piping has been lagged with Philip Carey four-ply air cell insulation, and steam lines between different buildings with six-ply insulation of the same make covered with 2 ply of building paper wrapped with copper wire.

Jenkins valves are used throughout.

Feed-Water Piping and Pumps

A very flexible arrangement of the feed pumps and piping has been secured, which insures against interruption in the supply of feed-water to the boilers. Three outside packed feed pumps are connected up in such a way that they may feed either the boilers or the domestic supply. Two are usually run on the boilers, the third ordinarily being used for domestic supply, pumping water from a cold water well to a tank on the roof, and providing for all water requirements throughout the plant except for drinking. Any one of the three pumps may be connected to any one of three sources of supply, the condenser hot well, the cold well above mentioned, or the feed-water heater.

The feed line from the pumps to the boiler-room ends in a header, from which the separate feed lines to each boiler are run. Each line is provided with a valve at the header and between this valve and the boiler another connection is made to another header which supplies city water, or domestic water for filling up the boilers after washing down or for other purposes.

For washing down purposes another line is carried over the boiler settings, and is fed with city water. Outlets are provided between each boiler, and it is an easy matter to connect it up, the hose run it through the open manhole and wash down the boiler with little trouble.

The feed-water heater is of the Moffat type, made by Goldie and McCulloch.

Motor Load

A number of motors are used throughout the various shops and take their supply from outside sources. The bolt department line shafting is run by a 100 h.p. motor, the foundry clearing department by a 75 h.p. motor, the woodworking department by a 100 h.p. motor and the tool-room by a 35 h.p. motor. All these motors are of C.C.E. type, manufactured by the Canadian Westinghouse Co.

Mr. R. Simpson, of 178 Wellington St., Kitchener, Ontario, writes:

"I think it is a good thing for the engineer that POWER HOUSE is published twice a month. I have taken it for a number of years and have received some very valuable information from it. As to changing the price, personally I feel it is worth double the present price."

TELL THEM

When writing to advertisers using space in POWER HOUSE, it is desirable that our paper be mentioned as the source of information. Our advertisers appreciate this, and so do the publishers. Every time our readers do this they co-operate with us in making the real worth of POWER HOUSE known. Advertisers believe in POWER HOUSE, readers believe in it, and so do we. Let's work together to make it more effective in our general interests.

BOILER ROOM, MASSEY-HARRIS CO., BRANTFORD.

SHOWING STEAM HEADER OVER BOILERS

STORAGE OF COAL AND SPONTANEOUS COMBUSTION

Coal should be stored in small quantities as near to the point of consumption as possible. Small coal piles rarely ignite from spontaneous combustion. Coal should be stored near the point of use to avoid re-handling, extra transportation and the degradation of size which follows each rehandling. For these reasons the bureau would advocate storage, so far as possible, in the bins and yards of the ultimate consumer, thus dividing the risk of loss from spontaneous combustion. If large storage piles are necessary, certain general principles must be borne in mind. The generation of heat is the result of slow oxidation of the coal surface. The oxidation is much more rapid from freshly mined coal or from freshly broken surfaces. The oxidation rate increases rapidly with increased temperature. Different coals have different oxidizing rates. These facts lead to the following recommendations:—Where there is choice of coal to be stored, that having the lowest oxidizing rate should be chosen, if known. Between two coals, that which is least friable, and therefore which presents the least total coal surface in the pile, should be selected.

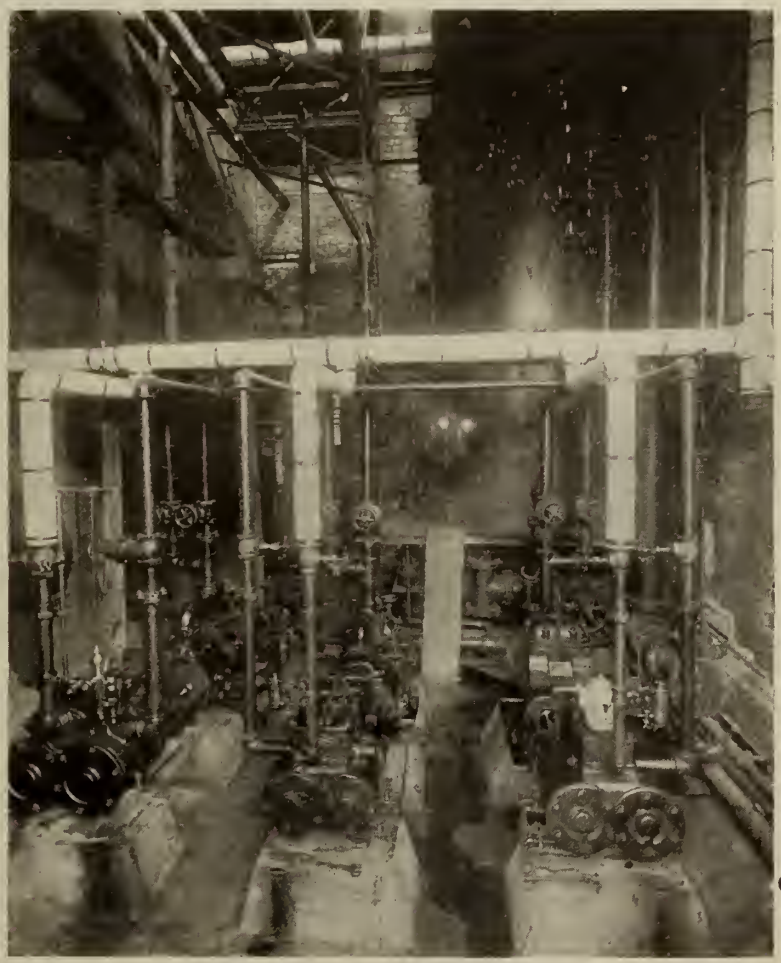
The method of handling should be such as to produce the least freshly broken coal surface. The coal should be as cool as possible when piled. Piling warm coal on a hot day is more likely to produce spontaneous combustion. The coal must be kept from an extraneous source of heat. Alternate wetting and drying of coal during piling is to be avoided if possible. The fine coal, or slack, is the part from which spontaneous combustion is to be expected. Piling of lump coal where possible is therefore desirable.

In the process of handling, if the lump coal can be stored and the fine coal removed and used immediately, the practice prevents spontaneous combustion in coals which would have otherwise given trouble. The sulphur content of coal is believed by many to play an important role in spontaneous combustion. The evidence on this point is still conflicting, but to play safe, it is desirable to choose coal having a lower sulphur content when choice is possible.

Coal piles should be made so that there is ready movement of air for ventilation throughout all parts of the coal pile. This is the condition when the entire pile is made of coarse lump coal. With ordinary coal piling this is difficult. The surfaces of coal piles should be so exposed as to allow the pile to cool; or else the coal should be so stored that air circulation within the pipe is very small. When the air circulation is reduced to a minimum, as in air-tight bin, with no opening in the bottom, the oxygen of the air is soon removed and the mass of the coal lies in an inert atmosphere, except for small local circulation near the surface. Air-tight bins are usually impracticable, but the following practice is recommended to approximate these conditions:

In making a coal pile of mixed sizes, the coal should be so handled as to make a homogeneous pile and prevent the segregation of coarse and fine coal. This frequently determines the most desirable machinery for unloading coal. It is common practice to limit the height of a coal pile, this for two reasons:—A pile too high crushes the lower layers of coal, producing more fines; the larger the pile the less the heat-dissipating surface there is exposed in proportion to the heat generating capacity of the pile. Twelve feet in height is a common limit.

Whatever precautions are taken in choice and handling of coal, provision should be made for keeping track of the temperature rise in a coal pile and for rapid rehandling of portions of a pile in case of excessive heating. In a coal pile covering considerable area, it should be so subdivided that in case of spontaneous combustion of a portion, the heat will not be transmitted to the whole pile, thus accelerating the heating of portions of the pile which normally would have remained cool.



BOILER FEED AND DOMESTIC PUMPS.

The Thirtieth Annual Convention of the C.A.S.E.

Delegates, Visitors and Exhibitors Spend a Pleasant and Instructive Three Days at Brantford—Business and Pleasure is in Equal Proportions—The New Officers of the C.A.S.E. and Exhibitors' Association

By T. H. FENNER, Editor Marine Engineering

WITH thoughts unclouded by the dark shadows of war and its attendant calamities, the delegates of the Canadian Association of Stationary Engineers met to celebrate the 30th annual convention of their order. The city of Brantford, rich in natural beauty and historical associations, was the chosen venue, and the arrangements made for the entertainment of delegates and their friends by the local lodge and the Exhibitors' Association left nothing to be desired. The only factor that fell down on the job was the weather man, who sent along a sample of his wet goods, which however much needed by the surrounding country, could have been well dispensed with, or at least postponed for a couple of days later.

However, neither delegates or exhibitors allowed a little thing like inclement weather to upset their plans. When the proposed outdoor events were banned by Jupiter Pluvius, they took up a strategic position in the capacious Brantford Armories and pulled off the hair-raising athletic programme with great success. The hardwood floor proved as good for track purposes as the greensward, and though as far as we know, no records were broken, very creditable times were made by the various contestants.

The Convention Hall

The problem of finding a suitable hall for the convention was a difficult one, but the local lodge solved it by taking possession of the emergency hospital, a one-storey wooden building adjacent to the armoury.

This gave the first requirement, space, and the advantage of a ground floor location for the various exhibits, some of which were heavy. Great credit is due to Mr. Gordon Keith and Mr. Betton of the Exhibitors' Association, who worked hard and long to give the bare interior a more pleasing appearance. With the aid of canvas, crinkly paper, and much goodwill they achieved wonders. Indeed, the citizens who visited the hall hardly recognized it as being the same building.

Monday night saw practically all the decorations completed, and the majority of the exhibits installed. Tuesday morning saw the official opening of the convention, when the big guns of the association and the exhibitors fired their salutes of welcome to delegates and visitors.

Official Opening

The official opening was scheduled for 10 a.m. and the mayor of Brantford was down for the opening speech of welcome, However, his worship failed to appear, or to send any explanation of his absence. Bro. W. Welsh, President of the Brantford Lodge, in a few direct words, declared the convention open, and was followed by E. L. Webster, Secretary of the Brantford Convention Committee. W. Cooke, President of the C.A.S.E., replied, followed by C. Z. Schrag, President of the Exhibitors' Committee; Lieut. L. Archibald, Fred W. Raven, Secretary N.A.S.E., and C. Z. Wyse, Educational Secretary of the N.A.S.E. Mr. Welsh, in the course of his remarks, mentioned that this was the second convention held in Brantford, and that but three of the charter members of the lodge were still in evidence. Lieut. Archibald, of the Dart Union Co. and past president of the Exhibitors' Association, is but lately returned from a prison camp in Germany. He enlisted in the Flying Corps and was captured when his machine was forced to descend in the German lines. He told an amusing story of the German commandant of one of the camps he was in. This officer spoke very good English, some of which was distinctly colloquial, the only trouble being he sometimes failed to realize the exact meaning of the slang he used. On the occasion of the arrival of a batch of prisoners he had them lined up in front of him while he impressed them with a sense of German superiority.

"You English think you know a few things, and so do the French, but we Germans, we know dam-all."

This last expression is very common in England to signify an absolute negation of knowledge.

Lieut. Archibald, in expressing his gratitude to his fellow members of the Exhibitors' Committee for the parcels of food sent him, told a story illustrative of the value of food to a hungry man. At the camp he was held in, the chief article of food was a liquid remotely resembling coffee. One of the English prisoners who had a good supply of money, observed a fellow-prisoner with a piece of the black bread that was occasionally issued. This was about four inches square. The Englishman tried to buy it, his final offer being a sum equivalent to $20, and this failed to induce the owner to part with the unsavory morsel.

The afternoon session was devoted to a meeting of the C.A.S.E. executive, while the ladies of the party paid a visit to some of the Brantford factories.

The evening was devoted to lectures about which more will be said later on in this report.

The Second Day

During the morning the C.A.S.E. executive were busy with association affairs, while the delegates and visitors had an opportunity of visiting the exhibits. These represented a great variety of power plant necessities, and the representatives of the firms were on hand to explain the uses and points of the articles displayed.

Following is a list of the exhibits:

James Morrison Brass Mfg. Co., Toronto.
Goldie McCulloch & Co., Galt.
Mason Regulator and Engineering Co., Montreal.
R. Sexton Fire Brick Co., Toronto.
Thomson Gordon Co., Toronto.
Allen General Supply Co., Toronto.
H. Mueller Mfg. Co., Sarnia.
Canadian Allis-Chalmers Co., Toronto.
Dearborn Chemical Co., Toronto.
Kitchen R. R. Signal Overall Co., Brantford.
Dart Union Co., Toronto.
Jenkins Bros., Montreal.
Quaker City Rubber Co., Toronto.
C. A. Dunham Co., Toronto.
Kerr Goodwin Machine Co., Brantford.
Garlock Packing Co., Hamilton.
John H. Hall & Sons, Brantford.
Dunlop Tire & Rubber Co., Toronto.
Empire Mfg. Co., Toronto.
France Packing Co., New York.
Chapman Double Ball Bearing Co., Toronto.
E. J. Philip & Sons, Toronto.
Lunkenheimer, Cincinnati.
Equipment Specialty Co., Toronto.
V. B. Anderson Co., Cleveland.
Power, New York.
Canadian Manufacturer, Toronto.
Power House, Toronto.

After lunch everybody adjourned to the Armoury and took up favorable positions for viewing the sports.

The first event on the programme was by far the most exciting. This consisted of a hockey match, between teams representing the Engineers and Exhibitors. The hockey sticks used were corn brooms, the puck being an undersized Association football. Both teams went at it in deadly earnest, and had some of the blows aimed connected with the ball, the resulting concussion would have been heard in Toronto.

However, the ball had a propensity to be a little above or a little below the spot aimed at, so all that happened was a graceful spin on the part of the swatter.

The umpire, Mr. Keith, being built, as one gentleman expressed it, "for comfort rather than speed," let some doubtful plays get by, but on the whole was satisfactory.

The Exhibitors won by one goal to nothing, which represents the play fairly well.

The combination of high heels, high speed and high polish (of the floor), proved too much for one of the contestants in the married ladies' race. She es ayed to slide home instead of running, and collected a considerable amount of dust, which liberally carpeted the floor.

The various events were well contested, and the afternoon was voted a huge success, and a fitting overture for the evening to come.

The evening's entertainment in the convention hall consisted of the prize giving to the winners of the afternoon contests, a sale of curios in aid of the local hospital, songs and speeches. Mr. E. B. Curzon of Montreal opened the musical part of the programme with "Long Live the King," following with "When the Bell in the Lighthouse Rings" as an encore. His fine baritone voice showed up well in these numbers. Miss Powell of Brantford, gave a very pleasing soprano solo, and Miss Emma Jackson, a very clever rendering of one of Mr. Dooley's soliloquies on the "Comforts of Travelling."

Mr. E. Hetherington of Galt displayed a very pleasing tenor, and Mr. Jack Armor, of New York, convulsed the audience with a snappy monologue. In the absence of W. C. McGhie, Mr. Mosely ,of the Board of Examiners of Stationary Engineers, spoke on the new licensing laws and graded certificates.

Mr. C. B. Turner had charge of the sale of curios for the Brantford Hospital, and this netted $30.80. An orchestra was in attendance and provided the accompaniments for the singers, besides playing several pleasing selections during the evening.

The Educational Side

One cannot help but feel that this side of the convention, which is one of the utmost importance, did not receive the support to which it was justly entitled. As a past member of the organization the writer recognizes the scope there is for developing this end of their activities, and was surprised to see the attendance so poor at the various lectures given. This was particularly noticeable at the lecture on turbines, which was jammed in at the end of the concert Wednesday evening, when time was extremely limited. This resulted in what might easily have been a very valuable contribution to the business of the convention, being reduced to a mere skeleton, and the writer sympathizes with the lecturer in the remarks he made at the opening of his lecture. The writer would suggest that for future conventions the subject matter of the lectures be printed, and issued to all the members of the various lodges some time beforehand. In this way the delegates would be familiar with the text, and in a position to bring up points for discussion. After all, the object of a convention is not purely the spending of a good time. It is due to the other members of the lodges that their chosen delegates shall have something to show for the expense incurred other than pleasant memories.

Ontario Government's Offer.

The Ontario Government, through Mr. McLachlan, informed the delegates that they were equipping at various centres, well-furnished class rooms. These would be thrown open for the use of the engineers, and the Board of Education was desirous of consulting with representatives of the C.A.S.E. as to the precise form in which they could best help their members from an educational standpoint. This progressive and helpful offer from the Government was well received by the delegates, and no doubt will be taken advantage of in the near future.

The Lectures

Mr. Flanagan, of the C. A. Dunham Co., gave an illustrated lecture on "Steam Heating," showing the growth of the art from the primeval fire in the cave. He also gave instances of right and wrong ways of making connections of steam heating mains and branches.

Mr. I. J. Tait spoke on refrigerating, illustrating his points by lantern slides.

Mr. D. M. Medcalf, Chief Boiler Inspector for the Province of Ontario, read a paper on "Causes of Boiler Failure." He had a choice collection of boiler plates and tubes, which had figured in accidents. These he explained in detail, making a very interesting half hour.

C. J. Porter of Hamilton, gave an illustrated lecture on various types of generators.

The lecture on turbines, by Mr. J. M. Brown of Hamilton, should have been the most interesting feature of the convention, as far as the delegates were concerned. As we said, the lateness of the hour and the scant attendance detracted from its value. Mr. Brown thoroughly understands his subject and has his heart in it, and deserved better support than he received.

The Officers.

The officers of the Grand Lodge for 1919-20 were elected as follows:

Past President, W. Cook, Belleville; 1st Vice-President, G. E. Moll, London; 2nd Vice-President, D. L. Webster, Brantford; 3rd Vice-President, Fred Harper, Kingston; Sec.-Treasurer, John Hale, Hamilton; Conductor, Ross C. Leach, Toronto; Doorkeeper, Geo. Lee, Ottawa; Delegate to N.A.S.E., W. Cook, Belleville; Alt. to N.A.S.E., S. Balmfirth, Toronto.

The next convention will be held at Woodstock, Ont.

The Exhibitors' Association officers were elected for the coming year as follows:

Past President, C. N. Schrag, Toronto; President, Jas. Mock, Montreal; 1st Vice-President, J. E. Fitzgerald, Montreal; 2nd Vice-President, Grant Cole, Toronto; Treasurer L. L. Archibald, Toronto; Secretary, Gordon C. Keith, Toronto; Asst. Sec., Geo. M. Wilkinson; Chairman Exhibits, A. Betton, Toronto; Entertainments, B. Curzon, Montreal; Reception, R. Sexton, Montreal.

COOLING-AIR MEASUREMENTS

At present no accurate method is in common use for determining the efficiency of the turbo-alternators, nor is any standardized conventional method in use in this country. Although the purchaser, since the efficiency of the turbo-alternator is usually expressed in terms of the rate of steam consumption in relation to the output of electrical energy, has little economic interest in the accurate determination of the efficiency of the alternator, the matter is of considerable interest to him, since the alternator efficiency is an indication of the quality of the materials and the excellence of the design. With turbo-alternators of even moderate size the stray loss may be as high as five or six times the ohmic loss in the stator copper, and in the opinion of some authorities may prove to be one of the factors that will limit the output of electrical energy obtainable from a single unit. The usual practice is either to ignore the stray loss or to determine it by a substantially conventional method.

Modern turbo-alternators invariably have forced ventilation, and except for the relatively small amount of heat dissipated from the external surface of the stator all the losses except the bearing losses are carried off by the cooling air. Hence if the volume of air flowing through the machine in unit time and the average increase of temperature that the air undergoes in absorbing the losses are known the total losses on load can be calculated without difficutly. This method, the principle involved in which was the subject of a paper read by Professor R. Threlfall before the Institution of Electrical Engineers in 1903, is the "air heating" method, and Professor Threlfall described the means by which sufficiently accurate measurements of the air volume and temperature can be obtained, provided certain simple precautions are taken. An alternative or "calibrated air-temperature" method which does not involve measuring the air volume consists in ascertaining the increase of temperature in the cooling air caused by a loss of known magnitude in the alternator, and deducing the total losses from the observed temperature rise of the air on load.

Economizers and Economizer Practice

This Article, One of the Series on Power Plant Management, Deals With the Economizer and Its Usefulness as an Aid to Boiler Room Economy. Features of Operation Are Also Discussed

By ROBERT JUNE, Mechanical Engineer

OF all accessory equipment in the boiler room, the economizer has the oldest history, and, in many ways the most secure position. It was in 1845 that Edward Green developed economizer design and construction to a point of practical utility, and the apparatus has been in more or less general use ever since. Curiously enough, America, with her apparently insatiable demands for industrial efficiency, has never adopted the economizer to anything like the extent which Europe has, nor has she accorded it, when adopted, the degree of appreciation and recognition to which it is entitled on merit.

For the economizer does possess merit, in ways which we shall discuss, sufficient to recommend it to the serious consideration of thousands of power plant operators, whose boiler rooms are not now equipped. But before taking up the question of what the economizer does, let us see what it is.

Economizers are of two general types.

(a) Integral, directly connected with the boiler.

(b) Independent, not directly connected with the boiler.

Fig. 1 is a good example of the integral type. The installation, which is to be found at the power plant of the Kansas City Light & Power Co., consists of six 1,300 h.p. B. & W. boilers, with economizers,built of standard drums and tubes of Sterling boilers superimposed. The use of Sterling boiler sections saved time in delivery, reduced cost, and at the same time satisfied the requirements imposed by the operating pressure, which was 300 lbs.

Figs. 2 and 3 (courtesy of Prof. Gebhart), illustrates the independent type, as exemplified by the Green economizer. The Sturtevant economizer, while differing in some details of design and construction, is of the same general type, and need not be separately described, it being understood that superior merit is not here assigned to either equipment, with reference to the other.

The independent economizer, then, consists of a series of rows of cast iron tubes, arranged vertically, in sections. The tubes are usually 9 to 10 feet high, and 4 5/8 in. in diameter. Sections of decreasing width are arranged across the main flue between the boiler and the stack, so that the gases of slow combustion must pass through the tubes on their way to the atmosphere. A bypass is provided for use when the economizer is down for cleaning or repairs, so that boiler operation need not be interfered with.

Top and bottom headers connect the various rows of tubes, and the headers are themselves connected to upper and lower branch pipes. Feed water on the way to the boiler is forced through the various sections of pipe, beginning near the stack, at the point of lowest temperature, and leaving near the entrance to the economizer, at the point of highest temperature.

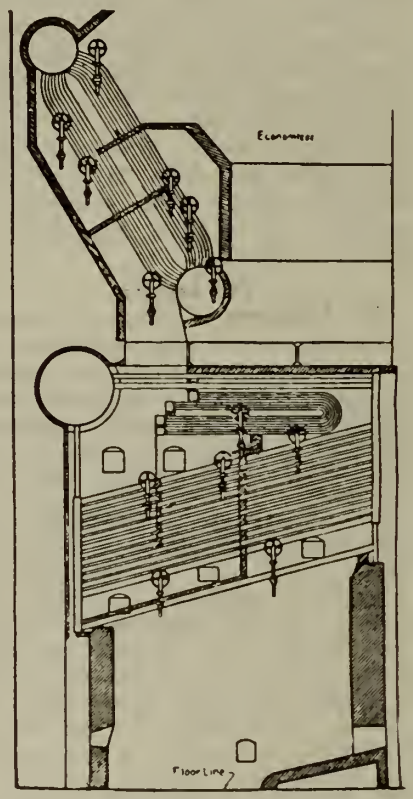


FIG. 1 INTEGRAL TYPE ECONOMIZER CLEANED WITH DIAMOND SOOT BLOWERS.

What The Economizer Does

The economizer takes in feed water at a temperature ranging from 50 degrees F. to 200 degrees F., and delivers it to the boiler anywhere from 100 to 150 degrees hotter, utilizing the heat of the flue gases which would otherwise be dispersed up the stack to the atmosphere. Off-hand, this looks like an opportunity to effect economies in operation well worth going after.

Without the economizer, the lowest limit to which the temperature of the flue gases leaving the boiler may be reduced, is, of course, the temperature of the steam, which is dependent upon the pressure, as shown in table 1.

With the economizer, the lowest practicable limit is that of the dew point of the exit gases. Under average conditions of boiler operation, only about 85 per cent. of the possible reduction between initial furnace and outlet gas temperatures can possibly be obtained. To obtain 95 per cent. it has been calculated that the boiler heating surface would have to be increased by 60 per cent. The impracticability of any attempt to gain economy in this manner is evident by a glance at the conditions of combustion.

When the combustion gases first come in contact with the boiler, the transfer of heat is very rapid, due to the great difference in temperature, but as the gases in their progress become cooler, the rate of transfer declines proportionately. If carried far enough, a point is reached where the amount of heat transferred per square foot of boiler surface is not sufficient to pay interest, maintenance and operation charges upon the surface involved. The calculation to obtain this minimum point is somewhat involved and need not be entered into here, it being sufficient to note that with coal at $3 per ton it ranges from 100 degrees difference between steam temperature and flue gas temperature if boilers are operated 24 hours per day, 365 a year, to 250 degrees difference if boilers are operated 10 hours a day, 300 days a year. We may assume 150 degrees to 200 degrees difference as the minimum in the average case. This means, finally, that our economical overall boiler efficiency is strictly limited, unless we can find some cheaper means, such as is afforded by the economizer, of transferring the heat to the water.

To take an example from actual practice, let us assume that a boiler operating at 180 lbs. pressure has been provided with sufficient heating surface, as is often the case, to reduce flue gas temperature to 560 degrees F. Assume water to enter the economizer at 90 degrees F. and water to be heated to 240

TABLE I.

Absolute pressure lbs. per sq. in.	Temperature deg. F.	Absolute Pressure	Temperature deg. F.	Absolute Pressure	Temperature deg. F.
100	327.6	160	363.4	250	400.9
110	334.5	170	368.3	260	404.4
120	341.0	180	372.9	270	407.8
130	347.1	190	377.4	280	411.1
140	352.8	200	381.7	290	414.3
150	358.2	210	385.8	300	417.4
		220	389.8	325	424.8
		230	393.6	350	431.8
		240	397.3		

degrees F. We then have average temperature of gases in the economizer $\frac{660 \text{ plus } 350}{2} = 455$ degrees, and of the water $\frac{909 \text{ plus } 240}{2} = 165$, giving an average difference in temperature of water and gases of 290 degrees. This is 1.6 times as great as the difference in temperature between the last pass of the boiler and the steam. Hence it follows that the economizer surface as a whole will recover 1.6 times as much heat per square foot as will the last square foot of boiler surface.

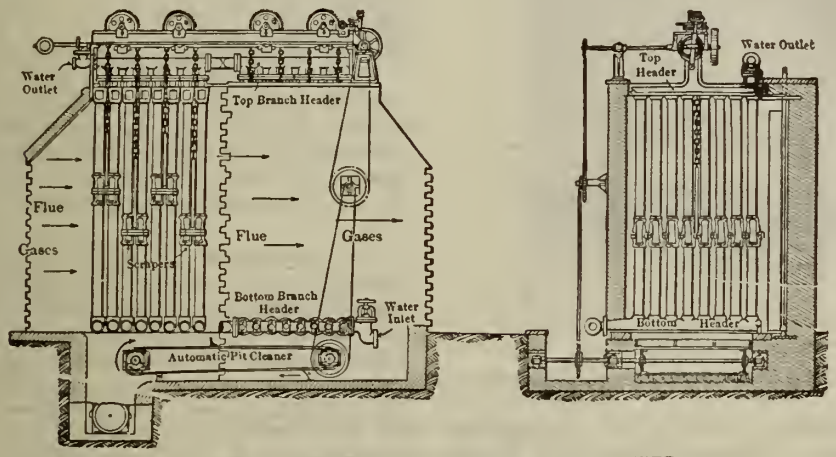

FIG. 2—CROSS-SECTION INDEPENDENT ECONOMIZER.

We may tabulate the advantages and disadvantages of the economizer as follows:

1. Fuel—a saving of 5 to 15 per cent.

2. Overall efficiency—a substantial gain where the boilers are forced and mechanical draft is employed. Highest possible gain when boilers are driven 200 per cent. or more above rating, using mechanical draft, and with electrically driven auxiliaries precluding a supply of exhaust steam, being available for feed water heating.

3. Decreased strain on boilers, due to higher entering temperature of feed water.

4. Increased flexibility. Large storage of hot water makes it easier to handle sudden peak loads.

Disadvantages of Economizers Are:

1. Initial cost—comparatively high, being in the neighborhood of $12 per boiler h.p.

2. Maintenance — comparatively high repair costs, due to soot scraper replacements. (This can be eliminated by use of mechanical soot blowers in place of scrapers.)

3. Overall efficiency—an actual loss where installation is made in connection with light chimney draft and boilers operating below normal rating.

4. Space required—the equipment is bulky, taking up considerable space. On new installations a larger boiler room than otherwise must be provided; in old boiler rooms installation can only be made at considerable expense or alterations.

Points to be taken into account when considering the installation of an economizer are as follows:

(a) Flue gas temperature—the higher the temperature the greater the economy.

(b) Boiler pressure—if 250 lbs. or over, economizers are indispensable.

(c) Boiler rating—the greater the load on the boiler the more necessary the economizer.

(d) Initial feed water temperature—In some cases an economizer is desirable even with initial temperatures of 200 degrees F.

(e) Exhaust steam—if the use of electrically driven auxiliaries eliminates exhaust steam as a possibility for heating feed water, an economizer is desirable.

(f) Purity of feed water—with impure feed water the formation of scale inside the economizer tubes may seriously affect the efficiency of heat transmission.

(g) Cost of producing draft — if chimney draft is to be depended upon, an extra height of stack, costing from 20 to 40 per cent., will be required. With mechanical draft power required ranges from one to four per cent. of main generator output.

(h) Extra cost for high pressure—cost for installation increases rapidly above 250 pounds pressure, on account of extra heavy materials required.

Some of the facts entering into successful and economical economizer operation will next be noted.

Gas Temperatures

It is important to know the temperature of the flue gases entering and leaving the economizer. Either a mercury thermometer or an electric pyrometer will answer the purpose. A recording instrument is preferable, since a permanent record is made to which reference may be made at any time. By means of this record the losses caused by air infiltration and dirty tubes may be determined at any time.

In inserting the pyrometer tube locations at the entrance and exit points of the gases should be carefully chosen. Do not place the tube behind the damper or anywhere else where there is likely to be a pocket of dead gas. Choose a point in the middle of the flue, and be sure that the hole through which the instrument is inserted is sealed tightly about it, so that there will be no air infiltration at this point, with consequent error in records, as well as loss in efficiency.

Water Temperatures

Mercury thermometers placed in the inlet and outlet pipes will show the water temperatures. Recording thermometers are preferable for this service, both from the standpoint of accuracy and efficiency of operation.

The function of the economizer is to heat the feed water and without continuous temperature readings the operator in charge has no idea how well results are being secured. It is not desirable from a mechanical standpoint to operate an economizer under such conditions as would cause steam to form in the economizer itself, yet this condition might arise with either a slight increase in the temperature, or an increase in the weight of the waste gases passing through the apparatus.

Air Infiltration

Due to the peculiar construction of headers, dampers, section walls, etc., the economizer offers many opportunities for air infiltration. Frequent checks should, on this account, be made of the entrance and exit temperatures of both gas and water, and frequent analysis should be made of the CO_2 in the entrance and exit gases. A drop of 1 to 2 per cent. in the CO_2 through the economizer may reasonably be expected, but where the drop exceeds this amount something is wrong and rigid in-

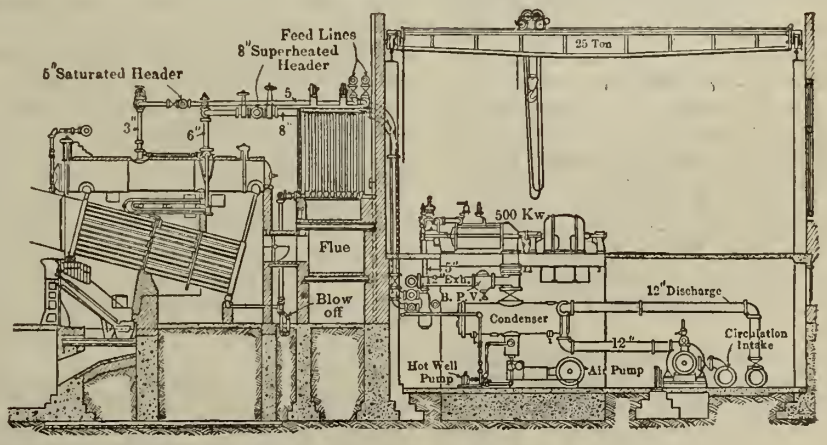

FIG. 3—LOCATION OF INDEPENDENT ECONOMIZER IN TYPICAL POWER STATION.

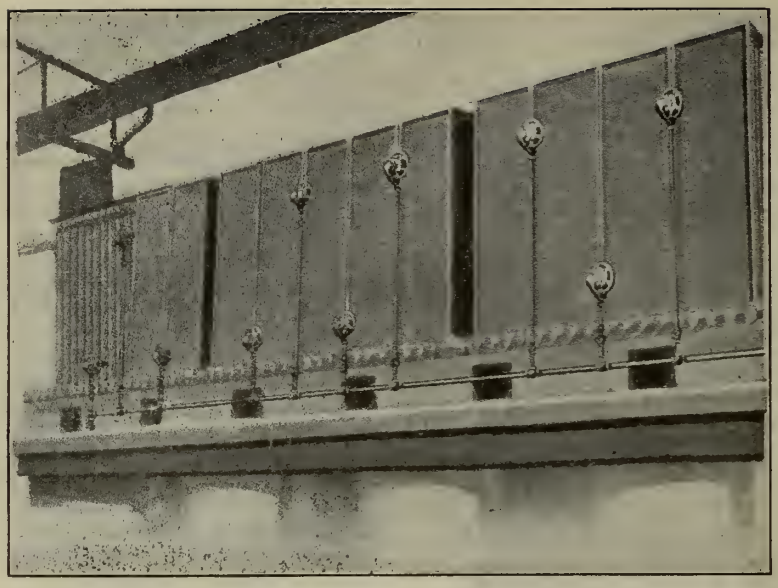

FIG. 4—INDEPENDENT TYPE ECONOMIZER CLEANED WITH DIAMOND SOOT BLOWERS.

vestigation should also be made.

In searching for air leaks, use a torch or candle, paying particular attention to cleaning doors, damper shafts, and the walls of the gas flue between the economizer and the boiler. Do not take it for granted that low gas temperatures mean efficient economizer operation. Constant checking, particularly of CO_2, is your only safeguard.

How Shall The Economizer Be Cleaned?

This question, until a few years ago, was always answered in one way, as far at least as the independent type of economizer was concerned. This answer is no longer always given, but before considering the alternative let us examine scraper construction.

Due, perhaps, to lowered temperatures and slower movement of the gas there is a great tendency toward soot deposit on economizer tubes. As soot is the best preventative of heat transference known, being several times more effective than asbestos in this respect, it must be removed. In scraper construction each tube is encircled with a set of triple overlapping scrapers which travel continuously up and down the tubes at a slow rate of speed. The apparatus for working the scrapers is placed on the top of the economizer, outside of the chamber, and the motive power is supplied either by a belt from some convenient shaft or small independent engine or motor. Power required for operating the gear is approximately one h.p. per 1,000 square feet of economizer surface.

Now, there are three important disadvantages to the use of scrapers which have led engineers to look elsewhere for a solution of the soot problem in economizers. These disadvantages are:

(a) Heavy initial cost of scraper mechanisms.

(b) Constant repairs required due to wearing out of scrapers and other moving parts.

(c) Cost of continuous power to move scrapers.

In addition to these disadvantages the scraper construction does not permit a thorough cleaning of the tubes. The scrapers embrace two tubes, and clearance is required, consequently there is a certain thickness of soot accumulation which is never scraped off the tubes. Investigations have proved that the scrapers frequently glaze this accumulation into a hard, enamel-like scale that can only be removed by tapping.

As an alternative to the scraper, engineers have been turning in increased numbers to the standard cross-element, revolving type of mechanical soot-blower. As far as the integral type of economizer is concerned, the mechanical soot blower has been the only type of cleaning device considered.

Fig. 1, which shows the integral type of economizer at the Kansas City Light & Power Co., illustrates the application of Diamond soot blowers for cleaning purposes. Each economizer has six soot blower units, with 19 nozzles each, on each side. Six minutes actual blowing time is required to blow the soot from the economizer, and the steam consumption is about 2,600 pounds of steam.

Fig. 4 shows the adaption of mechanical soot blowers to the independent type of economizer. With revolving units permanently installed between the tubes and regularly used several times each day, the heat-resisting soot is given no opportunity to collect. The tubes are kept perfectly smooth and clean at all times, and consequently the general efficiency of the economizer is very greatly improved.

Where new installations are being considered, it should be remembered that mechanical soot blowers can be installed at the outset, thus entirely eliminating the cost of scrapers. Furthermore, it is possible to plan on the use of horizontal tubes in the economizer, thus permitting the installation of baffles to hold gases in contact with tubes for a greater length of time.

The Solvay Process Co. reports the following results of a test made to determine the actual comparative value of mechanical soot blowers and scrapers on their economizers:

	Entrance gas temperatures	Exit gas temperatures	Difference
With scrapers	437 deg.F.	383 deg.F.	54 deg.F.
With mechanical soot blowers	437 deg.F.	320 deg.F.	117 deg.F.

This test fairly indicates the very marked advantage of mechanical soot blowers over scrapers, and it is to be anticipated that economizer practice of the future will tend more and more toward the use of mechanical soot blowers.

The Booth-Hall Company, designers and builders of electric furnaces, announce the removal of their executive and sales offices to rooms 1007-8 Hearst Building, 326 West Madison Street, Chicago. This change was necessitated by new arrangements in connection with the manufacturing of their electric furnace equipment. Increased facilities for turning out standardized furnace equipment has been provided with a large manufacturing company located in Chicago.

Furnace Installation.—The Electric Furnace Construction Co., Finance Building, Philadelphia, reports the following orders received for "Greaves-Etchells" electric furnaces; Lancia Co., Turin; Bresciana Co., Brusche. They have also successfully started up new furnaces at the Daimler Motor Co., Coventry; at the Tyne Electric Steel Foundries, Ltd., and also a furnace for Kayser-Ellison & Co., Ltd., Sheffield, designed for up to 15 tons cold metal or 20 tons hot metal process.

Explosion an Accident.—The case of the explosion that occurred at the Davie Shipbuilding Co. plant, Lauzon, Levis, Que., that resulted in the death of one of the employees named Robert Henley, and serious injury of another named Xavier Levesque, was cleared up and found to be an accident. It appears that among the scrap recently purchased by the Davie Shipbuilding Co. included some piping that had been purchased from one of the Dominion munition plants. The pipe that caused the accident was placed on a bench to heat the T that could not be loosened, and naturally the workmen or no officer in connection with the works had the least idea that there was cordite or guncotton in the pipe. The pipe did not, however, burst with the force of the explosion. It appears from the investigation that fireman Henley was in the act of passing the mouth of the pipe lying on the bench, when the heated pipe went off, and he caught the full force of the contents, which stripped him of his clothing, and knocked him heavily against the wall, which resulted in his death.

Municipal Electrical Engineers Meet

Recent Convention in Niagara Falls Notable for Opportunity Given to Members for the Inspection of Power Developments Now Working and Contemplated

THE annual convention of the Association of Municipal Electrical Engineers of Ontario was held at the Clifton Hotel, Niagara Falls, Ont., on the 19th, 20th, and 21st of June. Within sight of the majestic cataract that has made possible the power development and the industrial supremacy of the Niagara frontier, these members of the electrical profession, with the dull roar of the falling waters ever resounding in their ears, compared notes and discussed ways and means of extending still further the already tremendous business of power production and distribution made possible in the province of Ontario by the existence of the giant cataract, truly regarded as one of the most famous of nature's marvels.

In selecting the Clifton Hotel as headquarters for the convention the officers of the association no doubt had in mind the fact that of all the accomplishments wrought by the brain and hand of man in the last century, none are exceeded by the significance of Niagara harnessed. They no doubt had in mind the idea that no man is able to measure what this turning of the waters into turbines for the production of electrical energy can mean to this or succeeding generations. They were undoubtedly impressed with the fact that this development did much to initiate, and is chiefly instrumental in maintaining this electrical age.

While the members of the electrical fraternity attending the convention were intent on exchanging professional experiences, and making such recommendations and changes in electrical practice as wider experience always demands, they by no means neglected to contemplate and admire the grandeur of the spectacle lying constantly before their eyes, and this is not strange since Niagara has caused the mighty of many lands to ponder over its majesty. Sovereigns and rulers of many lands, persons high in official position, characters of celebrity in art, in literature and in science, from almost every land on the face of the earth, have stood in awed silence at Niagara's mighty brink.

On Thursday, June 19th, the members of the association and their friends registered at the convention headquarters, and after hearing the presidential address by Mr. O. H. Scott of Belleville, Ontario, they gave attention to a paper on Routine Handling of Consumers' Accounts, by Mr. R. C. McCollum, Auditor Municipal Accounts, Hydro-Electric Power Commission of Ontario. Mr. McCollum presented to his audience the results of a careful survey of the practice in this connection of Public Service Corporations in Canada and the United States, leading to the conclusion that a card system gave the most concise and satisfactory results, and such system he stated was in general use in the Hydro Electric system's various offices.

On Thursday evening the convention dinner took place in the dining-room of the Clifton, and several members and guests were called upon for a few remarks. Mr. A. Monro Grier, K.C., President of the Canadian Niagara Power Co., was the speaker of the evening, and his most interesting address, tinged throughout with a philosophical and advisory strain, received at its conclusion the well-deserved and extended applause of the gathering.

Mr. Grier in his remarks endeavored to impress his audience with the idea that they might draw many lessons from their contemplation of the great cataract, especially from the idea of the strength of unity that it conveyed He directed attention to the fact that the power development in Ontario was primarily due to the fact that a vast number of individual drops of water were continuously falling over the brink of a gigantic precipice, and that in their unity lay their power, so also he pointed out the greatness of any nation lies in the unity of purpose of its people. His address throughout its entire length was conceded by all present to be most interesting and instructive in its relation, not only to the electrical field, but to the Empire and Canada as well.

On Friday morning Mr. W. L. Goodwin presented his plan, describing the correct relation the various electrical industries held to each other. He dwelt upon the many anomalies that existed in the electrical field, particularly between the manufacturer, the jobber and the contractor and dealer, and his remarks were followed by an extended discussion by the members of various aspects of the plan in its relation to general practice among the trade.

On Friday afternoon Mr. C. E. Schwenger, Engineer of Distribution, Toronto Hydro Electric System, presented a paper on "Overhead Distribution Systems." in which he described the problems of distribution encountered in the City of Toronto. His paper was full of technical data of interest to the electrical engineer, and brought forth some lengthy discussion on the part of the members, who expressed in their numerous queries the appreciation they felt for the labor entailed in the preparation of a paper of so technical and instructive a nature.

On Saturday morning the members of the convention were transported en masse to the Chippewa Development Scheme now being worked out by the Hydro Electric Power Commission. Here again they were impressed by the details of the installation of one of the greatest hydro-electrical power developments yet attempted, which will upon its completion some years hence, result in a further development of the remarkable industrial progress that has taken place in the Niagara and Ontario district.

After an inspection of the Chippewa project the visitors hied themselves away by motor car and lake steamer to the more monotonous scenes of their daily avocations, which they doubtless perform with renewed energy because the thought of the resistless and ceaseless current of one of Nature's greatest wonders has charmed their senses, putting new vigor and spirit into their minds and hearts.

FIREPROOFING MATERIAL

Coating or impregnating with precipitated double borate of zinc and aluminium in a colloidal medium is a new method of fireproofing. A mixture of zinc sulphate and aluminium sulphate is dissolved in hot water, the double borate being next precipitated by adding a suitable proportion of borax, and the precipitate is then suspended in a colloidal solution such as that formed by dissolving 4 oz. of gelatine in a gallon of water at 90 degree C., and adding 12 oz. of ammonium chloride. On strongly heating, the compound is converted into an amorphous glaze, very resistant to high temperature and flame.—M. E.

Graphite and kerosene are most often used in America for the purpose of removing scale which has formed in boilers. Their action seems entirely mechanical. Opinions as to the desirability of their use vary from enthusiastic commendation to absolute condemnation. Their use seems generally approved by practical men, but a warning against the practice is given in a leaflet published by the United States Bureau of Mines, in which it is pointed out that neither should be used in boilers in which there is already a heavy deposit of scale, as the loosening of this material and its accumulation in the bottom of the boiler is apt to lead to blistered and bulged plates. Both graphite and kerosene should be used very cautiously. Kerosene, if used in excessive quantity, is apt to distil over and attack gaskets.

A New Prime Mover; the Still Engine

The Following Article Abstracted by "The Engineer" From a Paper by Frank D. Acland Read Before the Royal Society of Arts Gives Some Interesting Information Relative to a New Development in Prime Movers. The Combination Here Described Gives Promise of Remarkably High Efficiencies

THERE are two methods of producing power by the combustion of fuel—either under boilers or within the main cylinders of combustion engines. The greater part of the world's power is still derived from steam, which, owing to its proved reliability and greater adaptability to the services demanded of it, holds the field in competition with its rival, the internal combustion engine, but the latter shows a far higher heat efficiency. Yet it cannot start itself; cannot develop its full power, except at full speed; is a poor performer at low speeds; can only operate on moderate overloads for short periods; and may cease to operate, owing to a small defect, without warning. So combustion engines have as yet made little progress in competition with steam in locomotive work, and have supplanted steam, but to a limited extest, in marine and stationary engines.

The maximum ideal efficiency of a heat engine is obtained where the difference existing between the highest and lowest temperatures of the working fluid is greatest in proportion to the maximum temperature, and here the internal combustion engine, with an initial temperature higher than the furnace temperature of the boiler, and even higher than the melting-point of cast iron, is capable of realizing better thermal conditions than any other form of heat engine; but in its turn it suffers from two disadvantages—it ejects its working fluid at a temperature too high for ideal conditions, and it loses heat energy to a regrettable extent in the cooling of its cylinder.

The possibility of combining in one engine the superior thermal cycle at the high temperatures and pressures of the combustion engine with the low thermal cycle of steam to deal with its rejected heat, and, in the same engine, to add the superior working advantages of the steam engine is the basis of work carried out by Mr. W. J. Still.

The Still engine is an engine capable of using in its main working cylinder any form of liquid or gaseous fuel hitherto employed; it makes use of the recoverable heat which passes through the surfaces of the combustion cylinder, as well as into the exhaust gases, for the evaporation of steam, which steam is expanded in the combustion cylinder itself on one side of the main piston, the combustion stroke acting on the other side. It increases the power of the engine, and reduces the consumption of the fuel per horse-power developed.

Its primary object is not to use the waste heat for raising steam, but first to use it in improving the thermal conditions of the working cylinder, and so ensure the maximum efficiency from the fuel burnt within it, diminishing, as a consequence, the heat lost in that operation. Since the maximum efficiency is obtained by combustion of the fuel in the cylinder, and the minimum by the evaporation of the water in the steam generator, it is evident that the larger the quantity of steam which can be generated per horse-power developed by the combustion cycle, the lower must be the heat efficiency of the whole machine.

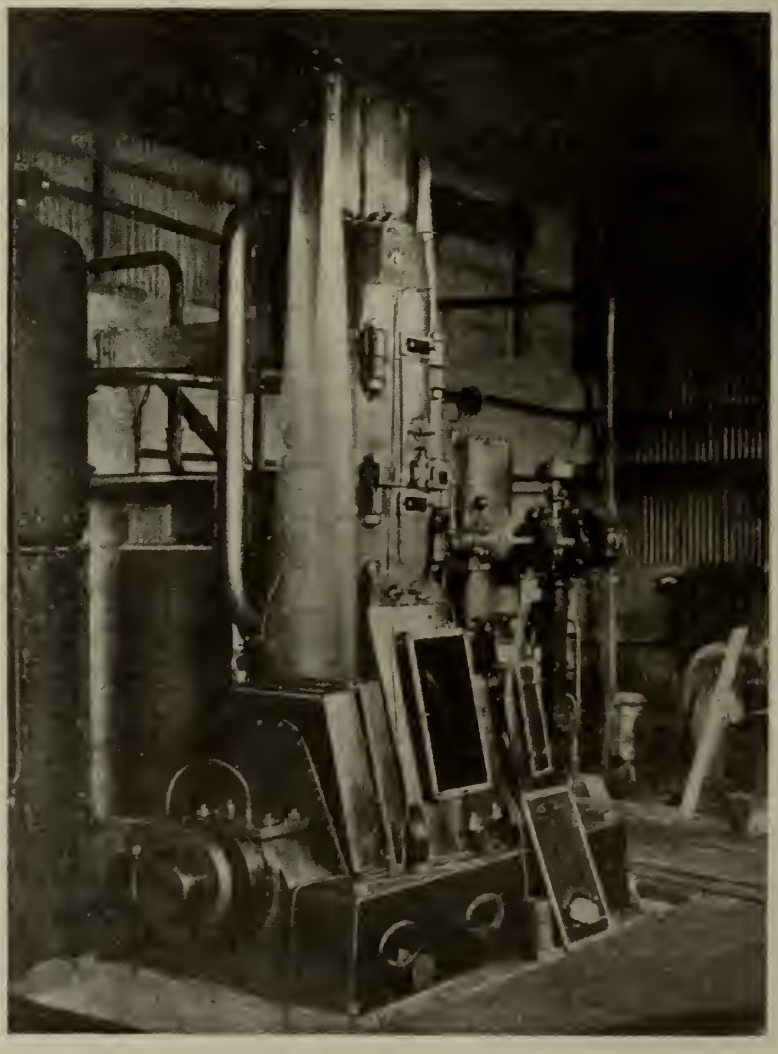

FIG. 1.—VIEW SHOWING STILL ENGINE IN OPERATION, RUNNING WITHOUT FLYWHEEL.

In the Still engine—see diagram—the jacket and cooling water form part of the circulating system of a steam generator, which may be an integral part of the engine or external to it. The cooling water therefore enters and leaves the jacket at a constant temperature, regulated by the pressure of the steam; the cooling is effected by converting the water into steam without raising its temperature. Excluding the radiation losses, which are kept low by lagging, all the heat which passes through the walls is thus usefully recovered in the water as steam. The temperature of the cylinder wall is uniform over the whole of its exterior surface, and the heat lost to the cooling water at each stage of the cycle—compression, combustion, and expansion—is diminished.

During compression, owing to the walls being at steam temperature, the incoming charge picks up heat instead of losing it during the greater part of the stroke, an advantage of the greatest value to the heavy oil types of Still engines, where an air charge is taken in at the full outstroke, and is compressed to a pressure where its increased temperature ensures the certain ignition and combustion of the fuel which is injected into it.

During combustion and expansion the uniform and higher mean temperature of the walls reduces the heat lost to

the jacket water. Some of the heat thus economized adds to the useful work on the piston, the balance passing out in the exhaust gases for recovery.

To ensure the maintenance in a practical and reliable manner of the temperature conditions which produce this efficiency during the combustion cycle, a departure from the design and construction of the cylinders of normal internal combustion engines is imperative. The cylinder of a Still engine consists of an inner liner, which is approximately one-third to one-fourth of the usual thickness; it is ribbed externally so as to add to its conducting surface and provide suitable passage for the cooling water, and it is reinforced by an outer hoop capable of withstanding the highest pressures to be met with in working. No failure of a cylinder of any kind has occurred, even under most severe, even abnormal test conditions, e.g., with mean combustion pressures of 180 lb. per square inch in a two-stroke engine, to which was added overload steam mean pressures of 70 lb., i.e., a total mean effective pressure per revolution of 250 lb. per square inch.

The Still engine may be of the constant volume or constant pressure type, or a combination of both; its losses to the cooling water are not the same as in a normal engine of either type, except in so far that they vary with the type, with the cycle, with the efficiency of the combustion stroke, and with the load. At normal and full loads, such heat units, in a Still engine, as pass into the jacket water, which is at steam temperature and pressure, are lessened and are wholly recovered without loss —radiation excluded—in overcoming the latent heat of the water and give off their steam in the steam space in proportion to the heat flow at these loads. At lower loads less steam is produced, until at still lower loads no steam at all is measurable. In other words, the jacket losses are practically eliminated.

The exhaust gases take a subsidiary, but important, part in the cycle; their usefulness in ordinary combustion engines, in raising steam, is limited to the amount of heat recoverable between the initial temperature of the exhaust and that of, say, 50 deg. Fah. above the steam temperature, after which the whole volume passes away to atmosphere at a still useful temperature, less a small percentage available for feed-water heating. But in the Still engine the exhaust gases, after raising their quantum of steam, are employed in preheating all the water required for the steam generated in the jacket water and in the generator. Trials at full efficiency over long periods and steady loads show terminal stack temperatures as low as 150 deg. Fah. The heat efficiency of the combined cycles is therefore exceedingly good, with an initial temperature of over 2,000 deg. Fah. and a final exhaust to atmosphere at 150 deg. Fah.

The quantity of steam capable of being generated from "waste heat" depends upon the efficiency of the combustion cycle, and on the load. Some years of experimental work prove that the weight of steam recovered may vary from a maximum of about 7 lb. per brake horsepower hour developed by the combustion cycle of a four-stroke constant volume engine at full load to a minimum at light loads which is hardly measurable, and which only balances the loss due to radiation.

The engine used for this research was of constant volume type, four-stroke. It first underwent a series of tests, so as to arrive at its "initial horsepower" as an explosion engine, i.e., without any power added by the steam cycle, and was carefully checked in this connection by comparison with well-known and authenticated trials carried out by the late Professor Bertram Hopkinson, F.R.S., and others. Though it was a single-cylinder unit with automatic inlet valves, its "initial horsepower" was rated on a par with the power given by four-cylinder sets with mechanically operated valves deduced from tests over very short periods under their best conditions.

The quantity of steam generated per "initial brake horsepower" from the jacket alone averaged 3.28 lb. per brake horsepower hour, and from the jacket and exhaust together 6 lb. per brake horsepower that, this being the average of the whole of the trials over periods varying from 20 minutes to over six hours. The final six hours of a 7½ hours' continued test gave a total recovery of 6.9 lb. of steam per initial brake horsepower. A whole series of these early trials was carried out under the supervision of C. Vernon Boys, F.R.S., whose sympathetic interest and encouragement is gratefully acknowledged as having largely contributed to the progress made since the inception of the system.

Normal load.—The average mean effective pressure from the combustion stroke was 90 lb. per square inch. The steam evaporated by the "waste heat" gave 14 lb. per square inch mean effective pressure on every return stroke.

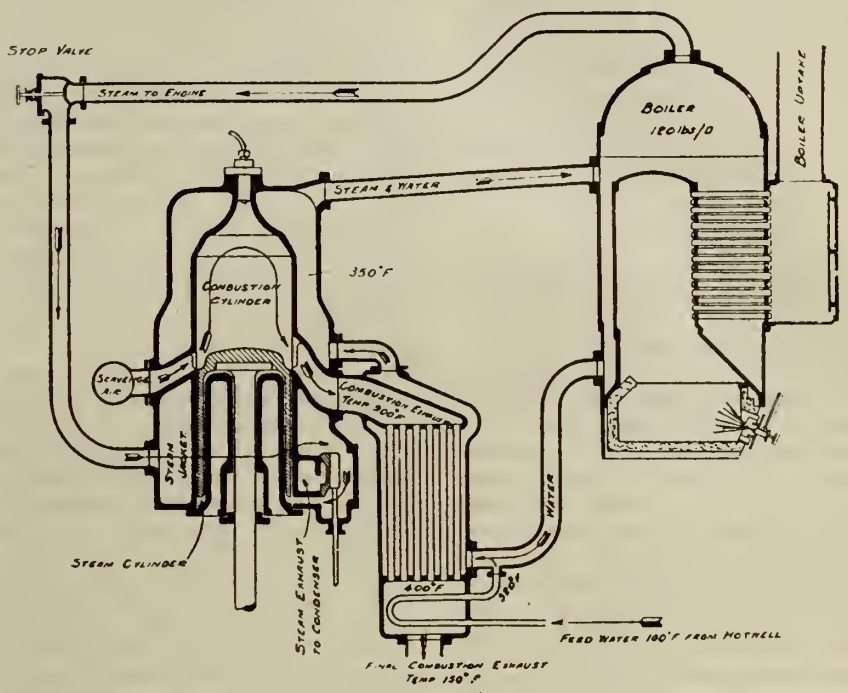

DIAGRAM ILLUSTRATING PRINCIPLE OF OPERATION.

This is equivalent to 90 + 28 = 118 lb. per square inch mean effective pressure in a normal four-stroke engine.

Overload.—By admitting additional steam generated by fuel under the boiler, the steam mean effective pressure was raised to 72 lb. per square inch; the total mean effective pressure was therefore equal to 90 + 144 = 234 lb. per square inch mean effective pressure in a normal four-stroke engine.

Gas Engines

The first experimental engine constructed was a two-stroke engine capable of developing 590 brake horsepower from three cylinders at 400 revolutions, bore 8 in. It was a high-speed engine, designed with special regard to obtaining data about the recovery of steam from waste heat (jacket and exhaust). It was first operated on town gas—540 B.Th.U.'s, and subsequently converted for oil fuel. Its efficiency was not high, owing to its being a two-stroke engine with a short stroke, but its consumption per brake horse-power was 15 cubic feet per hour (31.3 per cent. efficiency), a very promising result.

The outbreak of war prevented much progress being made in the design and construction of gas engines; but the

results achieved give great promise of future development, for with a combustion indicated efficiency of 36 per cent., radiation 4 per cent., boiler loss 10 per cent., there remains 50 per cent. for recovery; allowing 10 per cent. efficiency for the steam cycle, a gain of 5 per cent. is assured, and the total indicated efficiency of the engine will not be less than 41 per cent. If 20 per cent. efficiency is obtained from the steam cycle, as appears possible, the total indicated efficiency will be 46 per cent.

A gas engine which can give a brake thermal efficiency of 30 per cent. better than its predecessors, and which, by governor control alone can meet any demand up to and over 100 per cent. overload, while maintaining a good efficiency at that increased output, cannot be neglected.

Petrol and Oil Engines

Four-stroke engines for petrol and similar fuels have been built and tested ashore and afloat.

A three-cylinder set (marine type) capable of developing on its three small cylinders at 600 revolutions per minute 12.5 shaft horse-power at 90 lb. combustion mean effective pressure, without power from the steam stroke, gave on continuous running 16½ shaft horse-power under "waste heat" conditions, maintaining from the "waste heat" a steady boiler pressure of 100 lbs., with sufficient reserve for manoeuvring in narrow waters or bringing up. It would pick up very rapidly when ignition recommenced, and bring up the boiler pressure to normal in a few minutes.

With the addition of a burner below the boiler it would run continuously and develop 38 shaft horsepower at 750 revolutions. Monetary overload in proportion to the capacity of the boiler reached 60 indicated horsepower (51.5 shaft). Under steam alone the engine is a most satisfactory performer, but not economical.

The Still oil engine starts with the cylinders and pistons preheated. The air charge, from the moment of its entry into the cylinder, picks up heat from the containing walls and continues to do so during at least 70 per cent. of the compression stroke, with the result that the temperature necessary for firing with certainty the first injected charge of fuel is reached with a compression pressure 50 per cent. less than that required in a Diesel engine.

This fact is far reaching in its importance, for it gives to the designer great elasticity and freedom of application, for a Still heavy oil engine can be designed for constant pressure or constant volume, or both can be employed in the same engine by correct timing of the fuel injection. It claims for its combustion cycle an efficiency higher than that of the Diesel, less weight and space per horsepower, and for its combined cycle an efficiency not less than 20 per cent. higher than any prime mover which uses fuel as its source of heat.

The first engine designed for the use of heavy oil was of the opposed piston type, 16 in. diameter, 32 in. total stroke, revolutions 150, the combustion taking place between the two pistons with the steam generated by the jacket water and exhaust gases expanded at the back of both pistons—the steam passed from the auxiliary boiler through high-pressure and intermediate-pressure cylinders, and finally to the Still engine as a low-pressure cylinder—and thence to the condenser.

In a special engine subsequently constructed to meet special conditions—where the maximum power in minimum space was the main desideratum — the dimensions of the cylinder were:—Bore, 13½ in.; stroke, 22 in.; two-stroke cycle, opposed pistons; steam side as for low-pressure cylinder. It forms the basis of a six-cylinder set, two of them using high-pressure steam, which is compounded into the other four as low pressure.

The combustion takes place between the pistons, the steam acting on the return stroke at the back of both pistons. After a series of preliminary tests under steam alone, in which data was obtained for the various mechanical adjustments, the scavenge, compression pressures and temperatures, at various speeds, oil was injected for the first time. The engine fired its first charge without hesitation, and completed a series of tests of over two hours' continuous running, without adjustment, giving an output by gradually increasing the weight of oil admitted of 100, 150, 200, etc., up to 400 indicated horsepower at a maximum speed of 380 revolutions per minute, for which she was designed.

This unit has been subjected to many long and varied tests by representatives of various Governments, as well as to constant research work under severe conditions. Its best consumption of fuel —Admiralty shade oil—has been as low as .302 lb. per brake horsepower—scavenge pump not included—over a test of one hour's duration under normal waste heat conditions. It developed 330 brake horsepower for six hours at 360 revolutions per minute—a single cylinder—under waste heat conditions. It will develop 400 brake horsepower continuously with added steam, and has developed 540 brake horsepower at 380 revolutions over short periods. (Combustion mean effective pressure 128.2 lb., steam mean effective pressure 57.9 lb., total mean effective pressure 186.6 lb.) The thermal brake efficiency from below quarter load to full power is maintained at approximately 40 per cent. over the whole range.

With added steam from the boiler 5,000 brake horsepower would be obtained from two six-cylinder sets, with a weight of about 70 tons, including all auxiliaries and water, and extreme overloads up to 6,000 brake horsepower could be obtained.

The application of the Still system to commercial marine work is being developed in this country and abroad, the two-stroke single-piston type, in powers of 100 horsepower per cylinder and 400 horsepower per cylinder, having been adopted.

Engines of this type at 120 revolutions per minute, with a cylinder 22 in. diameter by 36 in. stroke, giving 4,200 shaft horsepower on two shafts, with all auxiliaries and water, would approximate 600 tons. A geared turbine plant in a similar ship would weigh 20 per cent. more, and would consume approximately 2,000 tons more fuel for a double journey lasting 1,000 hours.

Locomotives

The success already achieved in proving the principles to be correct, both in theory and practice, has led to a careful study, both here and abroad, into the application of this system to locomotive work. No high-powered locomotive engine, using heavy oil or gas in its cylinders, has been produced capable of economical haulage of heavy loads.

A Still engine designed for locomotive work would be capable of giving an efficiency at the rails of 30 per cent. over 90 per cent. of its running time—in other words, six times as good as the present locomotive; while during the accelerating period its efficiency would be at least 15 per cent., or three times as good. In surmounting long inclines with heavy loads, the engine would be capable of developing about four times the power which it develops at its most efficient or normal running load.

It is surely not unreasonable to expect that the application of the system here described should be put, without delay, to practical test for locomotive work, and especially so in view of the development and enormous expenditure contemplated in the electrification of railways. To give up the unit system of traction where the failure of one unit does not involve the failure of the whole, and to rely on what is, after all, a delicate and easily dislocated source of energy from central power stations, merely to gain a problematical 6 per cent. increase of fuel efficiency, seems to involve a risk far greater than the encouragement and development of novel forms of engines, which, whether gas or oil, may be evolved at the present rate of progress before the country is too far committed to such a gigantic and possibly dangerous experiment.

Discussion

The discussion was to a certain extent disappointing, in that it largely took the form of questions, and time did not admit of a reply by the author. Emphasis should, however, be laid on the point that the paper was confined to the setting forth of the principles of the Still engine, and from the remarks made it would seem that their correctness is beyond dispute. Sir Dugald Clerk reminded the audience of the previous attempt of Simon in 1878 to utilize the

waste heat of an internal combustion engine by converting it into steam, failure being due to the admission of the steam into the combustion chamber along with the explosive mixture. An interesting comparison was quoted by him of the Castner Kellner gas engines, which produced, when working on continuous full load, 2½ lb. of steam per brake horsepower at 100 lb. pressure, as compared with the 7 lb. per brake horsepower produced by the Still engine. Incidentally Sir Dugald mentioned that the efficiency of the solid injection submarine engines used in the British Navy was 36 per cent. The only criticism raised by Sir Dugald was that the reduction of the compression pressure from the 500 lb. per square inch in the Diesel engine to 300 lb. in the Still engine, while giving certain advantages, would cause the loss of a certain amount of the efficiency due to the higher compression.

Professor Watkinson had doubts as to whether the steam produced would be sufficient to cool the pistons if the engines were made in larger sizes than those already tested, and the author's reply on this point will be of great interest. He made a suggestion which appeared also to be in the minds of other speakers, that a higher efficiency could be obtained if the steam were to be used in a separate uni-flow engine or a turbine, but such a vital alteration would appear to eliminate some of the important advantages of the present plan. Professor Boys, who has been closely associated with the development of the engine, was interesting in his remarks about the inventor, who he said had foreseen all sorts of possible difficulties and experimented on each one at a time—a very important point—so that when it came to actual construction he was fully armed with facts and results and the course of the experiments ran smoothly. Professor Boys drew attention to the fact that the steam in the Still engine was used under even better conditions than in an ideal steam engine.

Mr. Stokes dealt chiefly with the political aspect of the new principles set forth, and urged the necessity of the Government examining fully into all prime movers before going ahead with their electrical schemes. Mr. Frank Bailey, following somewhat on the same lines, stated that the great economy of the Still engine might make it worth while to install comparatively small power units in factories, and so seriously interfere with the load factor of large central stations and vitiate the whole idea of the Government plan.

Mr. Martineau, who also had been closely associated with the Still engine, showed that the I.H.P.-B.H.P. efficiency of an ordinary internal combustion engine could be increased by 17 per cent. by converting it to the Still system.

Mr. Still, answering a question, said that lubrication of the Still engine had been effectively carried out by a mixture of oil and graphite, adding that the maximum steam pressure he had used was 250 lb. per square inch.

Sir Charles Parsons, in concluding the discussion from the chair, amused the audience by stating that in order to obtain the maximum power for a large cruiser before the war the design would call for 150 cylinders on four shafts.

POWER GAS

As power gas is likely to come largely into use in the near future it is interesting to recall that the first apparatus for its manufacture from coal dust and for the recovery at the same time of sulphate of ammonia, was designed and patented by Ludwig Mond, and built at Brunner Mond and Co's. Northwich works.

The advantages of using power gas can be summarized as follows: The cheapest quality of coal, even pit-head refuse, can be used, and, consequently, power can be obtained in addition to valuable by-products without the use of expensive steam coal. Very little labor, and that of only an unskilled character, is required. The heating value of the gas is equal to roughly, about 86 per cent. of the total heat energy contained in the fuel from which it is produced, and it can be obtained on a large scale for a mere fraction of a penny per 1,000 cubic feet. What this means will be realized when it is mentioned that one ton of rough slack will provide upwards of 150,000 cubic feet of power gas having a calorific value of at least 140 British thermal units per cubic foot. The quantity of gas required to produce an indicated horse-power-hour in a large gas engine varies, but may be taken as being about 50 to 60 cubic feet. One ton of low grade coal, gasified, and used in a modern gas engine, will produce at least 2,500 indicated horse-power-hours, or 2,500 horse-power for one hour. That is to say that a ton of this coal converted into power gas, will produce about 500 per cent. more power than it would were it burned under a boiler in the ordinary way and the steam used to drive an ordinary reciprocating engine. Taking the price of slack at as high a figure as 12s. per ton, delivered, the fuel cost of an indicated horse-power-hour obtained by power gas would not exceed one-twentieth of a penny.

It has been pointed out, and rightly, by the advocates of the use of power gas that in every steam plant working with a variable or intermittent load a considerable percentage of the fuel is wasted. Some loss under this head is unavoidable, but it was early realized that the employment of power gas reduces such standby losses to a minimum.

In the early forms of producer the apparatus was provided with a water seal so arranged that the ash, which is the only residue, descended into the water, from which it could be easily removed. The process of combustion was carried out at a comparatively low temperature, which not only prevented the formation of clinkers but provided against the destruction of any of the by-products. This was accomplished by blowing a blast of hot air and steam into the producer. The quantity of steam required when it was desired to recover the ammonia was equal to about 2½ tons for every ton of fuel gasified. Of this about two-fifths was afterwards recovered. When the process was first used comparatively little attention was paid to the recovery of the ammonia, and the quantity of steam used in such case was about one ton for every ton of fuel.

In connection with the plant a regenerator was used, through which the gas passed. In this part of the heat was transferred to the blast of air and steam on its way from the air-heating tower to the producer, the gas being cooled to a corresponding extent before it was delivered to the mechanical washer. Here a system of rapidly revolving dashers kept a fine spray of water passing through the gas, which not only reduced its temperature, but cleansed it from dust and particles of carbon. From this washer the gas passed into an acid tower, where the ammonia content was removed by a weak solution of sulphuric acid with which it was brought in contact, forming sulphate of ammonia. This solution was passed continuously through the stream of gas until it contained about 35 to 40 per cent. of sulphate. In order to provide for continuity fresh acid was introduced periodically and corresponding quantities of the sulphate liquor removed. This was then evaporated into solid form, after which it was crushed and sold as fertilizer, whilst the gas was passed into a cooling tower in which it was again thoroughly washed. Modern methods have improved to some extent on this process, but substantially it remains much as it did when it was first brought to the notice of engineers by Mr. Mond.—M. E.

Samuel F. Joor, a well-known consulting engineer of Chicago, has joined the American Steam Conveyor Corporation, Chicago, in a capacity of sales engineer. Mr. Joor has had wide experience in the conveyor field, at one time being western manager and sales engineer of the Jeffrey Manufacturing Company, and previous to that, with the Link Belt Company.

ERRATUM

Owing to an unfortunate error on the part of our composing room, one of the illustrations of the article on The Boiler Room of the Sheet Metal Products in the June 20th issue was shown inverted. The illustration referred to is at the bottom right hand corner of page 246 and shows the interior of the furnace looking towards the stoker.

English and American Water Softeners

A Description of Several Types of Water Softeners From Which a Good understanding of Their Operation May be Obtained—The Article Describes Several Types

By F. C. P.

THE accompanying drawings, Figs. 1, 2 and 3, show the carburetor of Wright's improved water softeners, developed from the designs of Player and Weddell at Tipton, England. The drawings, Figs. 2 and 3, show the details of the automatic gear and trip gear of this English water softener, considering the automatic inlet valve "A", Fig. 2. The float rod is adjusted so that the water is cut off below the overflow level. The dividing box, "B", is set level so that the water flows over it in a film of uniform thickness. It divides the water into two or more parts. The division is controlled by an adjustable slide, "C", so that any amount of water can be caused to flow through the wheel. This is what controls the exact proportion of re-agent passing into the softener.

It will be noted that the water wheel, "D", is mounted on ball bearings, "E", which are kept well packed with grease. There are two chain and wheels, "F" and "G", one on either end of the shaft. One of these is geared to a chain wheel driving the stirrers, "H", in the re-agent tank, which keeps the mixture stirred. The other chain wheel is geared to drive a bevel gear.

The re-agent supply measure, "J", is clearly shown; the water wheel, "D", gradually lowers the re-agent supply pipe by means of the screw, "K", and allows the mixture of lime and soda to overflow in proportion to the quantity of water entering the plant. The bevel pinion, which operates this screw gear, slides on the spindle and is controlled by the position of the trip gear as shown on drawing, Fig. 3. As the screw lowers, the trip gear comes into operation at a certain point, withdrawing the pinion from the bevel wheel, so that when this has been withdrawn the water wheel no longer operates the screw. This should be adjusted by means of the nut, "L", so that the pinion is withdrawn before the bottom bracket "M" comes into contact with the agitators, and also before the long screw, "N", has been unwound off the nut, "O". When the overflow pipe has reached this point it is very near the bottom of the tank, and it is time to recharge it.

In charging, the first thing to do is to wind the screw by the handle provided, so as to lift the overflow pipe to the top of the tank. During this time the pinion is held out of gear as it will be impossible to wind against the water wheel. The oil lever is examined, and it will be noticed that the screwed spindle, "N", is hollow. When the screw is at the top of the tank, it is filled with oil to the top of the spindle, by pouring oil down the hollow shaft. In starting the plant to work a definite number of pounds of lime and soda per inch deep in the re-agent tank is determined upon. The lime and soda are weighed and placed in the lime-slaking box, and sufficient water added to dissolve the soda and make a thin limewash, which is passed through the strainer, down into the re-agent supply tank, and the latter is filled to the necessary level with water, to produce the standard solution. The overflow pipe is then lowered until the re-agent is just commencing to overflow, when the water is turned on again and the plant is put into ordinary work.

The bottoms and bits of lime which pass into the re-agent with the charge

DETAIL OF AUTOMATIC GEAR.

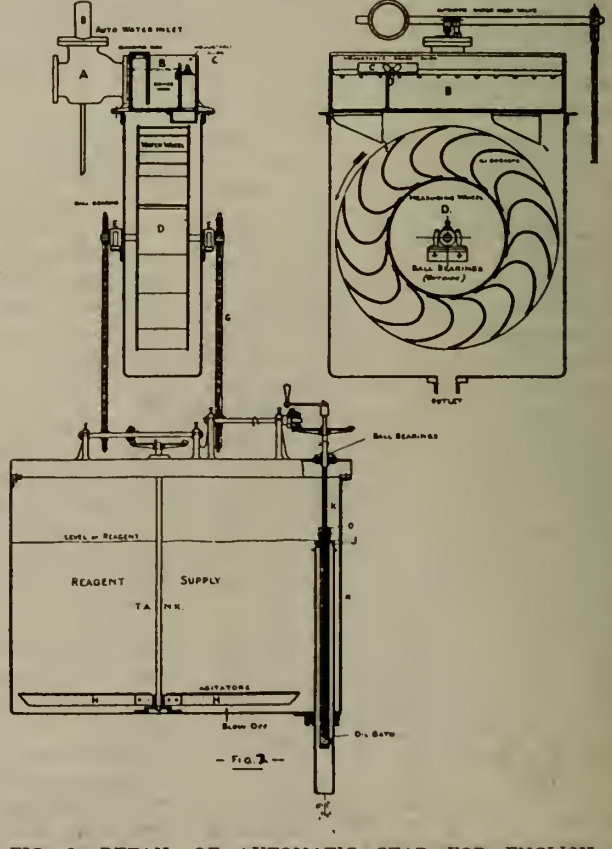

FIG. 2.—DETAIL OF AUTOMATIC GEAR FOR ENGLISH WATER SOFTENER.

are not allowed to remain in the supply tank indefinitely. This is emptied and swilled out at frequent periods. Particular care is taken that any accumulation around the rising and falling pipe is removed. The gland in the bottom of

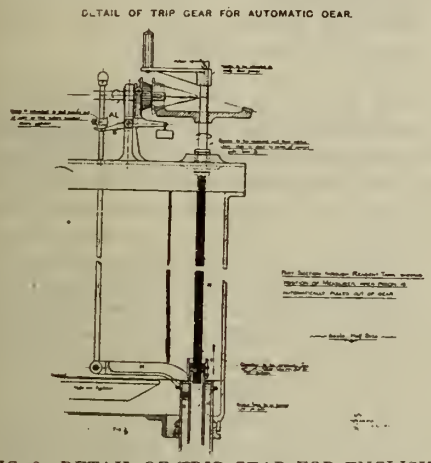

FIG. 3—DETAIL OF TRIP GEAR FOR ENGLISH WATER SOFTENER.

the tank through which this pipe works also receives attention.

In working the plant a constant feed is maintained so far as is possible. The re-agents are carefully added and this is done whenever necessary. Frequently water softeners are very badly neglected and allowed to run sometimes for hours, and even days together, without any re-agents being added to them. Another very common fault is to tip re-agents in in indiscriminate quantities. They should be accurately weighed and great care should be exercised in doing this.

In testing the hardness of the water the apparatus required is a 70 c.c. pipete or measure, two buretes to hold about 25 c.c.'s, an 8 oz. stoppered bottle, a white dish to hold not less than 150 c.c., and a small glass stirring rod. The re-agents required are Clarke's soap solution, decinormal sulphuric acid, and small bottles of silver nitrate and methyl orange. The water to be examined should be quite clear. If it is not it should be passed through an ordinary filter made from blotting paper in a glass funnel. Assuming the test to be of the softened water from the plant, three tests are required. To a few drops of the water on a white tile one drop of silver nitrate solution is added. There will always be a precipitate formed, but if it is white it will intimate that there is sufficient lime being used. If it is the palest tinge of yellow it will intimate that the quantity of lime being used is correct; if it is deep yellow or brown, too much lime is being used. In testing it is pointed out that to a fresh sample of 70 c.c. of water in an 8 oz. bottle it is necessary to add solution to a little at a time and shake vigorously after each addition until a permanent lather is formed. If 6 c.c's of soap solution will produce the lather, the water will be softened to 5 degrees. Clarke (i.e., it is always 1 degree softer than indicated by the soap itself). If a smaller quantity of soap is required the water is softened below this degree. If a larger quantity of soap is required the water is imperfectly softened and more re-agent will be required. The lather should hold for a considerable time when the bottle is at rest. If it disappears in two or three minutes, it is not permanent and more soap solution should be used. Another 70 c.c. of water should be filtered through a paper filter and run into a white dish. One drop of methyl orange should be added and decinormal sulphuric acid added a drop or two at a time until the sample just commences to turn pink. The number of c.c's of acid used should be noted. This should be multiplied by 5 and the result is the total alkalinity of the water in grains per gallon. This should not be much in excess of the hardness indicated by the soap test. If it is, re-agent, usually soda, is being added in excess and consequently wasted.

In the accompanying illustrations, Figs. 4, 5, and 6, may be seen several

American water softeners of the Eureka type, developed at Mishawaka, Ind. The photograph, Fig. 4, shows a large water softener of a capacity of 12,000 gallons per hour, working automatically in conjunction with a 50,000 gallon steel

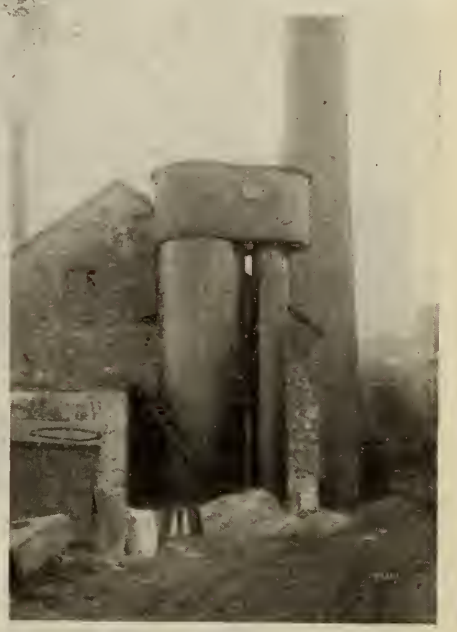

FIG 6—6,000-GALLON PER HOUR EUREKA WATER SOFTENER TREATING WATER. THE LOCKPORT PAPER CO.

storage tank of the Felters Co., of Lestershire, N.Y.

Two smaller American water softeners, of 3,000 gallons and 6,000 gallons per hour, may be noted in photographs, Figs. 5 and 6, the former being used for treating canal water for the Lockport Paper Co., at Lockport, N.Y., and the latter at the Lehigh Valley Silk Mills, at South Bethlehem, Pa.

The American automatic water softener and purifier is arranged so that the water may be supplied to the inlet valve in the tank either by pressure or gravity. A constant head is maintained in this tank, and the weight of the water falling on the wheel furnishes all the power required to actuate the plant. A portion of the raw water is diverted from the tank to a saturator where a clear lime solution of constant strength is manufactured. In this method none of the impurities in the lime come in contact with the water to be treated, thus there are no lime particles to go over into the piping and boilers. The alkalinity of the purified supply is practically nil so that there is not only no danger of foaming in the boilers, but the water is eminently suitable for all kinds of high-class work such as in laundries, wool-scouring, dyeing, etc.

There are provided a series of spiral plates to accelerate the precipitation of the impurities as the water travels upwards after the chemical reaction has oc-

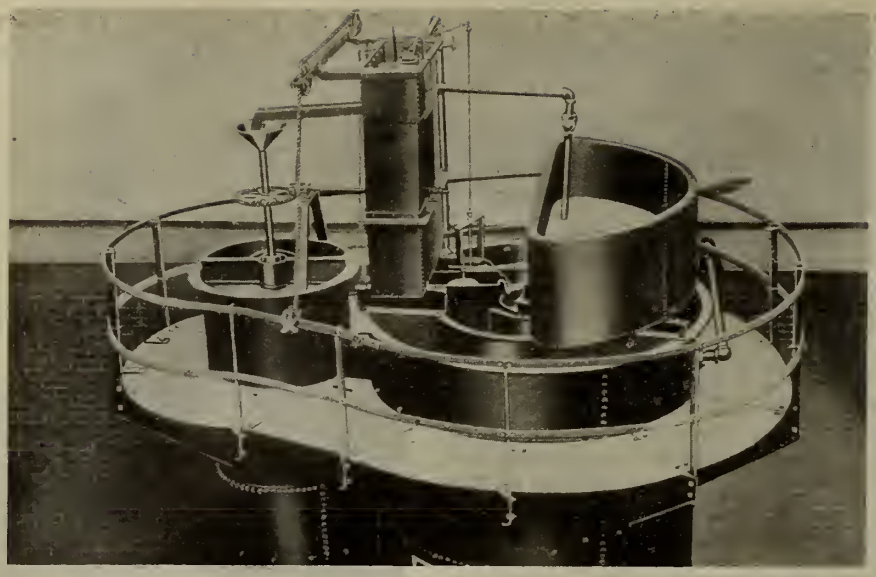

FIG. 5—DETAILS OF MECHANISM OF 3,000-GALLON WATER SOFTENER.

curred. The sludge deposited on these plates gravitates into the cone, from whence it is flushed to the sewer by simply opening valve for a few seconds daily. After leaving the spiral accelerators the water passes through a wood fibre filter into a reservoir, from which point it is drawn off for use, all scale forming matter and mud having been removed. The machine starts and stops automatically as water is required and will supply any quantity up to the rated capacity. The only attention necessary is about 20 minutes daily, which can be given by the engineer or other responsible employee without interference with his regular duties. It is never necessary for any purpose whatsoever to enter the machine.

In considering the water question, it will be stated that in converting water into steam there is, under the most favorable conditions, a great waste of heat energy. To minimize this loss has been the aim of mechanical men and inventors ever since the adoption of steam as a motive power. Heaters, stokers, economizers, pipe coverings, all tend to conserve the energy produced by combustion and to convert it into a potent factor. Manufacturers recognize these accessories as modern developments in steam engineering and consider them good investments.

Even at this age of advanced economies, when every department is closely scrutinized by experts to discover leaks and methods devised to lessen the cost of manufacture, it is marvellous that until the present day the very essence of economical steam generators, a non-scale-forming feed water should have escaped scientific treatment. Practically all natural waters are impregnated, to a greater or lesser extent, with soluble metallic salts, which tenaciously attach themselves to the boiler tubes and shell as the water is evaporated into steam, thus forming a cement coating that not only persistently resists removal but is also a non-conductor of heat. The extent of this non-conductivity is better appreciated when it is understood that most feed waters contain (in addition to other solid matter) considerable quantities of magnesia, which is extensively employed in pipe coverings to prevent the transmission of heat.

In many cases, after poison in the form of impure waters has been injected into the boiler, antidotes (boiler compounds) are administered in a vain endeavor to offset or neutralize the action of the poison. The compound cannot keep the impurities out of the boiler, and its most perfect theoretical action would only convert the solids into sludge, but it does not even do that, as engineers will testify. Aside from many of these, medicines have a baneful effect, causing leaky tubes, foaming.

Mechanical cleaners are expensive to operate, both as to power and labor required, and the more inaccessible parts of the boiler are never reached. In many plants a force of men are continually at work drilling out tubes. Exhaust steam feed heaters can remove from water only the carbonates (lime) as these are held in solution by carbonic acid gas, which is expelled by ordinary boiling at atmospheric pressure, and the carbonates, being thus released, are partially precipitated in the heater. The sulphates, however, which form the hardest kind of scale, are not affected in the heater, and pass on into the boiler, where they are precipitated by the high temperatures attained under pressure.

It is maintained that the utilization of waste steam for heating feed water is of vast economic value, but the supplying of non-scale-bearing water to the boiler is of much greater importance. The manufacturer is eternally studying how to reduce operating expenses, and scrutinizes with microscopic care every department in his factory. He is now tackling the power centre and must recognize that economy and efficiency in the boiler room must be of the most approved design.

WHAT A STEAM PUMP WOULD SAY IF IT COULD TALK

Please do not gorge me with oil, as it will give my steam chest indigestion. What I like is a steady diet which will enable my valves to work smoothly and with durability. A very small amount of oil fed to me steadily is the thing—it saves oil and repair bills.

Two or three times a year give me a good dose of coal oil to clean out any obstructions that may have accumulated in the passageways of my steam chest, or on the face or working parts of the valves and valve seat, or on the chest piston.

Do all you can to help me make a full length of stroke, as it means that I will use less steam and do better work. The adjustable collars on the valve rod will allow you to regulate the length of my stroke to a nicety.

By allowing me to make short strokes, you prevent my steam piston from getting in its proper cushion, which it would do if it could complete its full stroke. My steam piston is supposed to run up to the end of the cylinder and pass across the exhaust port, cushioning all the confined steam between said port and the cylinder cover. The hand wheels on the side of my steam cylinder are for controlling the amount of this cushion. For slow speeds these cushion valves should be shut tight. When running at ordinary speed or a high rate of speed, these cushion valves should be slightly opened.

Once in a while take a look at my water cylinder. See that the packing of the water piston is not set up so tight that it makes me grunt, producing unnecessary friction and wear. Or, perhaps the packing is too loose a fit, or is worn out and needs renewing.

Please see that my water valves are seating properly, because if they are not tight I cannot pump as much water as I ought to do for a given speed. Sometimes the springs on the back of my water valves need renewing or looking after. If you have not already provided a good suction air chamber for my water cylinder, you ought to do it, because it will prevent the water column in the suction pipe from slapping the face of my water piston at the end of each stroke in a harsh manner and so produce "water hammer." A good suction air chamber properly located, saves wear and tear, and makes a pump quiet running.

Please keep me nice and clean. I may not be of as much importance as your big engine, but there is no reason why I should not be kept free from dirt and grease. I hate to have oil slobbered all over my steam chest, or my stuffing-boxes left leaking.

You will find it pays to keep me in good condition, like a well-groomed horse. Treat me well and I'll serve you well and long.—"The Darling Digest."

Canadian Electrical Association Convene

Annual Convention Held at Alexandria Bay—Co-operation With Standards Committees in the Promotion of Engineering Standards Agreed Upon—Resume of Recent Progress in Electrical Engineering and in the Field of Prime Movers

THE Canadian Electrical Association held their annual convention at Alexandria Bay on June 27th-28th. With the cessation of war activities, interest centres around the improvement and standardization of equipment, better operation and other features rendered possible. Those connected with the electrical industry may well take a particular pride in the part played by it in the prosecution of the war to a successful conclusion, and while such has been the case many difficulties had to be surmounted and much deferred to a more favorable time. Such being the case the present time of reconstruction offers many opportunities for creative work and it was noticed throughout the papers and discussions as well as in the address by the president, A. Munro Grier.

Prime Movers

During the period of the war one of the features in the manufacturing life of this country was the plentiful supply of electrical energy available through the development of water power resources and the consequent conservation of fuel. This was brought out in the report of the committee on prime movers read by R. J. Beaumont.

The necessity of conserving the fuel supply of the country during the period of the war has turned the minds of all engineers and manufacturers to the necessity for economy in operation of steam plants. Recent progress has been to some extent concentrated on this phase of development. Considerable progress has been made in late years in the science of generating steam due to a better understanding of the combustion of fuel and the transmission of heat in boilers.

Boilers

Present day tendencies favor high steam pressures and temperatures, concentration of power and large unit capacities. The shell boiler has been practically eliminated for this class of service and modifications have been made in the setting and rating of water-tube boilers.

The application of insulating brick in boiler settings is now becoming better understood. It is generally accepted that the walls of a boiler furnace should be built of as few different kinds of material as possible and walls should be well bonded and homogeneous. Recent tendency has been to build walls of solid fire brick.

In order to preserve the furnace, side and bridge walls various expedients have been tried. Which is required is a furnace lining capable of withstanding the high furnace temperatures and blow-torch action; the constant heating and cooling effect and the abrasive action of the fuel bed.

Ventilated walls. special refractory materials, steam jets on side walls and high temperature cements have all been used with varying success.

The present tendency is towards higher boiler ratings. One of the principal factors involved in high boiler ratings is the coal burning capacity of the grate, or, in other words, stoker and furnace design. Draft loss at high boiler ratings is an important item to be considered and the character of the boiler feed water may readily become a factor in boiler ratings.

Power dump grates and clinker grinders seem to be coming into use. The Westinghouse Co. and the American Engineering Co. have these on the market, as well as several other concerns. The forced draft type of chain grate is now being used more extensively and with success in burning low grade fuels high in ash.

Higher steam pressures have been tried out in one or two plants in the U. S. The Buffalo General Electric Co. have recently placed in service a plant operating at 275 lbs. boiler pressure and 275 degrees super-heat, giving a total temperature of 689° Fah.

The Public Service Co. of Northern Illinois have an installation operating at 315 lbs. boiler pressure, 225 degrees super-heat, giving a total temperature of 615° F.

The general impression seems to be that the question of higher steam pressures is a boiler problem, and that turbines can be easily designed for operation at the higher steam pressures.

Steam Turbines

In recent years there has been a marked tendency towards the installation of units of large capacity, and during the past two years there has been a marked increase in the United States in units of the horizontal shaft type of approximately 30,000 k.w. capacity in order to meet the rapidly increasing density of the load.

The main source of trouble in large steam turbine units seems to be in the labyrinth packings and thrust bearings, which are apt to cause excessive vibration of parts, the breaking of buckets and dangerous rubbing of stationary and moving elements, which in extreme cases may result in permanent deflection of shafts.

The General Electric Co. states that new development work has been rendered difficult by war conditions, but a great deal of development work has been carried on nevertheless, to meet the requirements of the navy and Emergency Fleet Corporation. The loss of skilled labor has been felt very severely and to some extent has been reflected in the workmanship of the turbines built under war conditions. Another handicap has been felt in the difficulty of securing suitable quantities and qualities of materials required for the manufacture of turbines.

Considerable attention has been paid of late by many companies to the matter of fires originating within the generator shell of turbo-generators of the enclosed type, with the object of determining the means of minimizing the occurrence of such fires, limiting the extent of the damage and providing fire fighting equipment which can be quickly applied where it can do most good.

The origin of fires in turbo-generators during the past year seems to be fairly evenly divided between those external to the insulation surrounding the copper conductors, and those internal from the conductors themselves. The greater proportion of fires originating from sources external to the insulation seems to have occurred on three-phase systems operating without a grounded neutral.

The inspection and cleaning of turbo-generators at more frequent intervals would seem to be very desirable and to have a direct bearing on the liability to fires external to the windings. Every precaution should be taken to limit the amount of dirt and oil which may enter the generator, and many campaigns have standardized the installation of air

washers. Even with the best possible condition of cooling air it is evident, however, that dirt will lodge within the generator, and if a certain amount of oil vapor is also carried into the machine the coils and other surfaces may become smeared with grease. Good practice, therefore, would seem to dictate that machines should be opened up periodically for thorough cleaning and painting.

The extinguishing media which have been used in the past for turbo-generator fires are principally water, steam and carbon tetra-chloride (Pyrene). Practically only water and steam are looked upon at present with favor, inasmuch as large volumes of carbon tetra-chloride are required for any but very small fires, thus involving great expense and possible injury to operators from fumes.

Up to the time of the installation of permanent fire extinguishing apparatus for generators, water had been the principal medium used. With the advent, however, of permanently installed fire-extinguishing apparatus in generators the use of steam has received very serious consideration, and there is at the present time a wide difference in opinion as to the relative merits of steam and water in this connection.

The principle of operation in using steam differs from that in using water, in that displacement of air in the generator by steam is very largely depended upon to smother the fire. It is extremely important, in using steam, to shut off the supply of air to the generator as completely and promptly as possible. The wetting of the generator windings from condensed steam is probably also helpful.

Protective Equipment

It is rapidly becoming standard practice, particularly on larger units, for the manufacturer to bring out both ends of each phase winding to the generator terminal boards, so as to permit of the installation of current transformers between the terminals of the phase windings and neutral, which can be connected differentially with respect to instrument current transformers in loads between main oil switches and generator, so that in the event of a fault in the generator or its leads the balanced relay will immediately open the main oil switch, the neutral switch (if closed), and after a slight delay the field switch.

Before proceeding to fight any generator fire it is, of course, absolutely essential that the unit be disconnected from the line and the field opened. With the balanced system of protection this is done automatically in fires involved from breakdown of the conductor insulation on a grounded system. On other occasions these operations must be performed by hand as soon as it is evident that the unit is in trouble. It would seem very desirable to have a pilot light on the turbine gauge board connected across a generator potential transformer to indicate when the unit was generating, and also, perhaps, a red lamp to light on the operation of the balanced relay.

It will, of course, be necessary upon application of water to the generator windings to dry out the same on short circuit before again placing in operation. Experiences after floods have demonstrated that electrical generators may be immersed in water for some time with no serious damage resulting when thoroughly dried out before being placed again in commission.

Water Power

During the four or five year period prior to the war the manufacturers of hydraulic turbines made great strides in developing units of high efficiency and simple design. This was primarily obtained through the introduction of high specific speed single runner units. During this period a great number of low head plants were built, using single runner units of larger size than anything previously attempted. During the last four years, however, the activities in hydro-electric developments were greatly lessened and few new features of design have come out.

Efficiencies of 92 to 93 per cent. of runners have already been obtained in several plants, and it may be assumed that this is very near the maximum efficiencies that can be expected. To obtain a maximum over-all efficiency engineers are now carefully looking into the design of all passageways from headrace to tailrace. Particular attention is being paid to the design and efficiency of draft tubes for high specific speed runners. The tendency is towards the use of deeper draft tubes, with the idea of making the turn from the vertical to the horizontal direction at lower velocities than was previous practice.

There seems to be a difference of opinion as to the number and size of units to be installed in a projected plant; the tendency has been to look upon the water turbine as an almost fool-proof piece of apparatus; consequently plants have been equipped with as few and as large units as possible, thereby making a considerable saving in first cost, as well as in operating expense. Considering, however, that the reliability of a unit does not only depend upon the water turbine, but also upon the generator and auxiliaries, some designers of power plants incline towards comparatively small units, with less chance of breakdowns.

The single runner vertical shaft turbines for low and medium head plants have proven to be such a success that practically all new plants under this category are now being equipped with this type of unit.

Thrust Bearings

With the increase in size of large vertical water wheels and the consequent increase in weight of the rotating parts, the importance of satisfactory thrust bearing cannot be exaggerated, and a great deal of progress has been made in recent years.

The General Electric Co. has developed a spring supported thrust bearing which automatically adjusts itself to inequalities in loading, due to inaccuracies in workmanship and alignment. The bearing is not affected by the wobbling of the shaft. The rubbing surfaces are in a bath of oil, and the quantity of oil circulated depends upon the losses and cooling conditions.

Two of these bearings have recently been installed in the Cedar Rapids Plant of the Montreal Light, Heat and Power Co. in connection with the last two 10,800 h.p. units. These bearings are designed to sustain a load of 550,000 pounds during continuous operation at a normal speed of 55.6 rev. per minute. The Kingsbury thrust bearing has been adopted by the Hydro-Electric Power Commission of Ontario for the Westinghouse generators on the Queenston development. They are designed to carry a load of 900,000 lbs. at 187½ rev. per minute. The turbines for these generators have been awarded to the Wellman-Seavor-Morgan Co., and the two units will develop 52,500 h.p. each at the point of maximum efficiency, and 60,000 h.p. at full gate. The net head on the turbines will be 305 feet, and they will be of the single runner vertical type with a cast steel spiral casing.

Electrical Apparatus

In the report presented by the committee on electrical apparatus, emphasis was laid upon the advisability of standardizing lead markings and other features of designs of apparatus, such as transformers, and co-operation should be maintained and increased between the various operating companies, manufacturing companies and societies to this end.

The three-phase transformer is becoming more popular in many installations, and the general practice seems to be to instal transformers of just sufficient capacity for rated load, and to resort to water cooling for overloads.

The automatic sub-station for direct current is growing in popularity. There are at present on d.c. railway service seven sub-stations of 1,000 k.w. or over, and 49 between 300 and 600 k.w. All

have been operating automatically or semi-automatically for some time, and engineers would, it seems, be well advised to investigate the automatic substation as an economical proposition. D. C. sub-stations operating automatically are in continuous operation also, and some of these are of the straight outdoor type. Apparatus in automatic sub-stations should be more liberally rated and should be of the most rugged construction.

As sub-station apparatus the rotary converter with a capacity of 4,000 kw. appears to be about the upper limit of size. With the extension of the use of 60 cycles as a system frequency, the 60 cycle rotary has come more into prominence, although at times on railway service flashing is troublesome. The use of flash guards, arc cooling devices and high speed circuit breakers is expected to bring them upon a par with 25 cycle machines.

The general policy of operating all banks of transformers and distribution feeders on one bus with an auxiliary bus provided is maintained. The capacities so connected are running considerably higher than 10,000 kw., and this brings up the rupturing capacities of oil switches. To avoid considerable expense in changing over apparatus, as well as possible switch destruction, the use of reactors seems desirable. Attention is called to the neglect which usually falls to the lot of the air break switch. It is pointed out that the abnormal temperatures which are liable to be caused by oxidation create bad contacts.

Accident Prevention

The committee on accident prevention, Wills McLachlan, chairman, drew the attention of the association to the necessity for the elimination of tools with insulated handles. These tools are purchased from various manufacturers, and the insulation is oftentimes depended upon for the protection of life, where it is more a case of good luck than good management that fatalities are avoided. It was recommended that so far as possible tools with insulated handles be not used except for very high voltages where special tools are required, but that dependence be placed upon rubber gloves tested according to specifications. For some years past the Canadian Electrical Association have collaborated with the N.E.S.A. on the question of specifications for the purchase of rubber gloves and linemen's belts. These specifications have been completed and will form a tentative basis for further improvement or for adoption.

Lighting and Power Sales

Industrial lighting has shown considerable development, due no doubt, to the pressure of war work in the extensive production of munitions. In certain places in England and the United States it has been found that surprising results have been obtained in increased production, due to correct and improved lighting.

The sale of power during the period under consideration has been more or less normal. In almost every case where large systems are used it was found that the decline in load, due to the signing of the armistice, did not assume serious proportions, and that in some cases, where a wide service of large capacity was delivered, the amount of power delivered was practically only reduced for the period between the signing of the armistice and the end of 1918.

The present time is one of development, stabilization and return to prewar conditions. Numerous projects covering a wide variety of productions are under consideration and to meet this coming demand most of the larger power companies in Canada are either constructing plants or are preparing designs for future expansion.

The use of the electric stove is more than ever rapidly increasing. The effect of an electric range load on a distribution system is now rapidly becoming known, and has been found to be very satisfactory from the viewpoint of diversity.

The question of the cost of a range forms an interesting study, and there is no doubt that a need exists for what might be termed the "Ford of the electric range business." If a range could be sold for $60.00 it would add a great stimulus to their rapid introduction amongst people of very moderate means.

Synchronous motors are rapidly coming into popularity. This particular type of motor is, of course, more practicable, broadly speaking, in the larger sizes, owing to the somewhat more complicated operating features. A motor of medium size, say three to five hundred horse-power, has great value in correction of power factor on a system of fair size.

Service at Cost

In a paper read by E. P. Fredericks an outline was given of the many advantages of the "service at cost" plan as applied to public utility companies. These companies, and particularly those having to do with the distribution of electrical energy and city transportation, have been affected very materially by increased costs, and in many cases have been operating at a loss. As a means of offsetting this condition, and to insure that the municipality served will be receiving maximum advantages with the minimum of expense and the cheapest possible cost for fares, this plan has not only been proposed, but put into effect in a number of cities, with marked advantages. Cleveland, Des Moines, Cincinnati, Chicago, Philadelphia, and a number of other cities have already put the plan into force, and many more have been considering it very favorably.

Briefly, the service at cost plan provides that a public utility operating under it shall provide service at its actual cost, including operating expenses, maintenance, depreciation, taxes and 6 per cent. interest on the investment value. Investment value shall be money prudently and honestly invested, and this has been interpreted to mean money that has been invested as reasonably necessary for lawful purposes. It should be noted that 6 per cent. on the investment value does not limit the return on any particular security to 6 per cent. If the bonded debt should carry a lower rate of interest, more than 6 per cent. might be available for stock, but it is generally conceded that 6 per cent. is a fair return on the investment value. The actual value of each company accepting the plan is usually stabilized by some properly constituted authority, so that there may be no criticism as to inflated valuation.

The municipality or general public is protected by having its representatives on the operating board, and the advantages both to the municipality and to the company may be outlines as follows: It calls for close public supervision, it demands an improved service and the maintenance of the service at tis best standard. It demands efficient and honest administration, it provides for charges sufficient only to pay the actual cost of good, adequate service, and at the same time guarantees the integrity of the investment with the restoration of the credit of the utilities affected.

The Utilization of Off-Peak Energy

One of the most interesting papers read before the convention was that prepared by F. G. Clark, Chief Engineer Toronto Power Company, and read in his absence by Wm. Volkmann. Power Companies in many cases have considerable off-peak power which could be utilized to good advantage and which could be produced at a considerably lower cost than during peak loads.

The Toronto Power Co. operates one of the hydraulic plants at Niagara Falls, on the Canadian side, and a steam plant at Toronto. In 1915 this company established a research department having for its purpose, among other things, the increasing of the load factor of the system.

Finding that the manufacture of the gases oxygen and hydrogen by the electrolysis of water offered possibilities and that there was no apparatus on the

THE ELECTRICAL DEPARTMENT

Distribution System Nomenclature

An Article Dealing With the Proper Nomenclature of the Various Parts of a Distribution System and Explaining Their Relationships by the Aid of Diagrams

By TERREL CROFT

(Copyright, all rights reserved)

CONSIDERABLE confusion exists as to the precise meanings of the terms which are used to designate the different components of an electrical-energy distribution system. In the following paragraphs definitions are given for some of the terms most commonly used. These definitions are, it is believed, in line with the generally-accepted meanings of the words involved. Fig. 1 shows diagrammatically the important elements of a distribution system.

A transmission line comprises the arrangement of conductors over which electrical energy is transmitted from a generating station to a substation. In general, the distinguishing characteristics of transmission lines are that they operate at relatively-high voltages and extend for long distances. At B in Fig. 2 is shown the transmission line.

A tie line is a set of conductors used to interconnect two substations. A tie line may also operate at a high voltage and extend for a long distance, but is distinguished from a transmission line in that neither of the ends of a tie line originate in a generating station.

A transmission system is one over which electrical energy is transmitted from a generating station at relatively-high voltage to a distributing system, or to distributing systems

A distribution system is one from which electrical energy is distributed to consumers. As a rule a distribution system operates at a lower voltage than does a transmission system. However, it is very difficult to distinguish between a transmission and a distribution system, because (as P. H. Thomas states): "In any large system the functions of transmission and distribution merge into one another, because the principal consumers will ordinarily be many miles apart. Furthermore, there usually are several sources of energy feeding into the system at different locations. The transmission and distribution systems then resolve themselves into a net-work of high-tension lines to which are connected consumers and generators at certain locations."

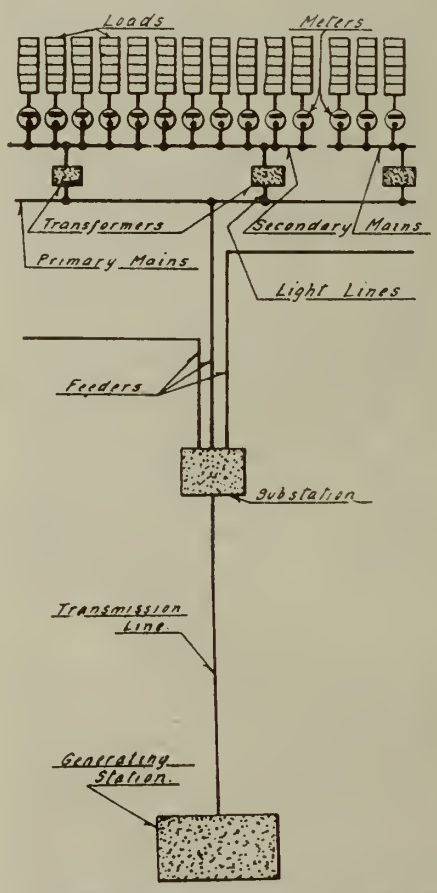

FIG. 1—THE ELEMENTS OF A DISTRIBUTION SYSTEM.

A feeder or feeder circuit is the set of conductors in a distributing system extending from the original source of energy in the installation to a distributing centre and having no other circuits connected to it between the source and the centre. The source may be a generating or substation. Feeders are indicated by the letter D in Fig. 2.

A sub-feeder is an extension of a feeder from one distribution centre to another, and having no other circuit connected to it between the two distribution centres.

A main (E and G, Fig. 2) is any supply circuit to which other consuming circuits—sub-mains, branches, or services—are connected through automatic cut-outs—fuses or circuit breakers—at different points along its length. Where a main is supplied by a feeder the main is frequently of smaller wire than the feeder which serves it. An energy utilizing device is never connected directly to a main, a cut-out always being interposed between the device and the main.

A sub-main (ES, Fig. 2) is a subsidiary, main fed, through a cut-out, from a main or another sub-main and to which branch circuits or services are connected through cut-outs.

A service (or a service connection, H, Fig. 2) is the set of conductors constituting an underground or overhead connection between conductors (usually belonging to a public service corporation) in a thoroughfare—street—and the conductors of an interior or isolated wiring system. A "service" provides a path over which electrical energy is delivered to the consumers.

A branch or branch circuit is the set of conductors feeding, through an automatic cut-out, from a distribution centre, main or sub-main to which one or more energy utilizing devices are connected directly, that is, without the interpositions of cut-outs. The only cut-out associated with a branch is the one through which the branch is fed at the main, sub-main or distribution centre.

A tap or tap circuit (Fig. 2) is a circuit, serving a single energy-utilizing

device, connected directly to a branch without the interposition of a cut-out.

A distributing or distribution centre in an electrical energy distribution system is the location at which a feeder or sub-feeder connects to the subordinate circuits which it serves. The switches and automatic cut-outs for the control and protection of the sub-circuits are usually grouped at the distribution centre. In interior-wiring parlance, a distribution centre is an arrangement or group of fittings whereby two or more minor circuits are connected at a common point to another larger circuit. A

CANADIAN ELECTRICAL ASSOCIATION CONVENES

Continued from page 283

market suitable for use on a large scale, having regard to economic features, research work was begun on the development of a type of cell which would prove satisfactory.

The result was the development of a type of electrolytic cell in which the electrodes operated at high densities and temperatures. Cells have been in operation at the company's Toronto plant for over two years, and have in this time fully demonstrated their commercial feasibility.

In the production of oxygen now so necessary in welding work and other mechanical arts, this step marks a considerable advance, enabling as it does, its generation to be carried on at a very much smaller cost than heretofore has been possible.

Officers

The following officers were elected for the coming year:

A. Munro Grier, K.C., President, 801 Dominion Bank Bldg., Toronto, Canadian Niagara Power Co., Niagara Falls.

E. A. Dunlop, M.P.P., 1st Vice-President, Pembroke Electric Light Co., Pembroke, Ont.

P. T. Davies, 2nd Vice-President, Southern Canada Power Co., Montreal.

A. P. Doddridge, 3rd Vice-President, Quebec Rly., Light, Heat and Power Co., Quebec.

T. S. Young, Hon. Secretary, 347 Adelaide St. West, Toronto.

Wm. Volkmann, Sec.-Treas., 12 Adelaide St. East, Toronto, Ont.

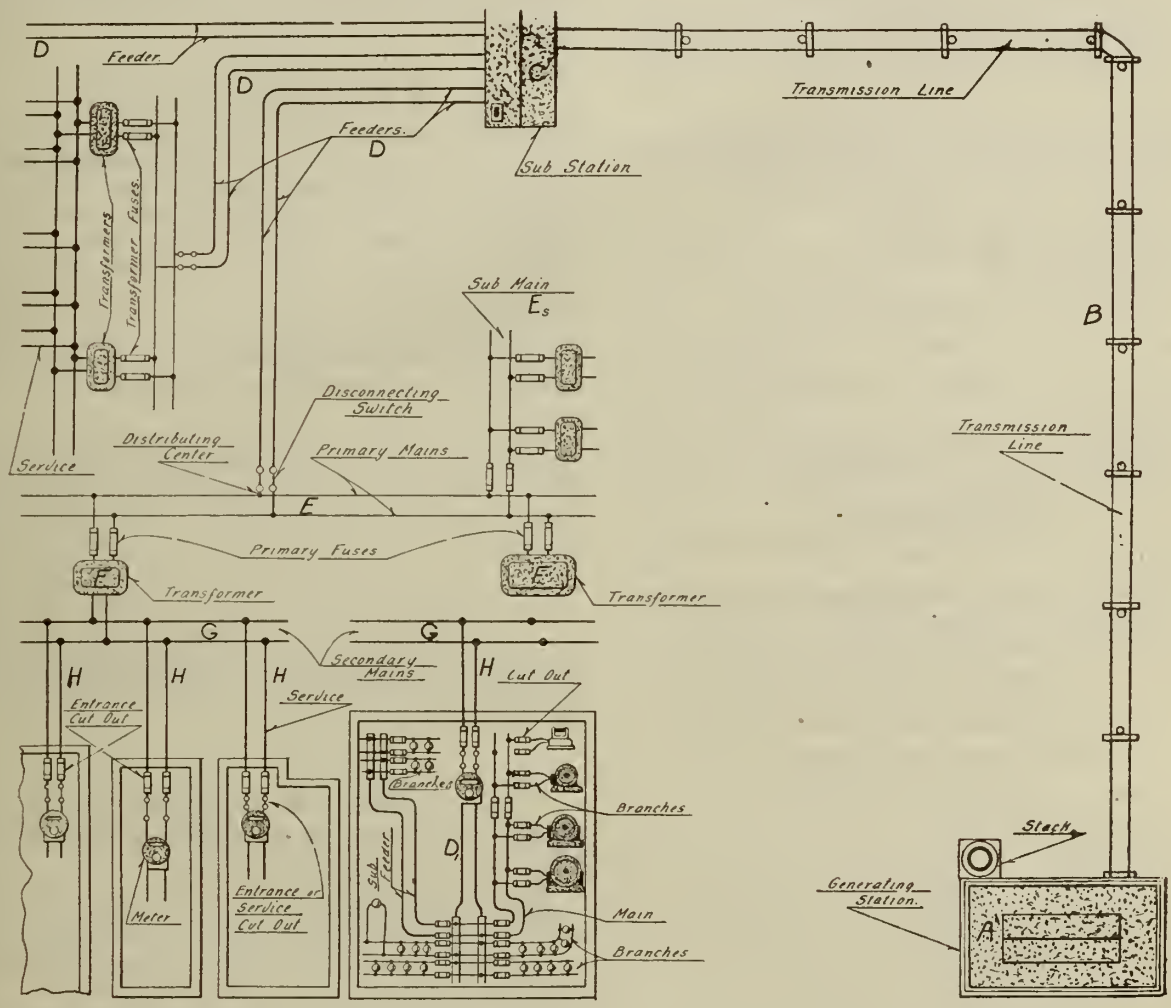

FIG. 2—PICTORIAL DIAGRAM INDICATING THE ELEMENTS OF AN ELECTRICAL ENERGY DISTRIBUTING SYSTEM

panel box is one form of a distribution centre.

The nomenclature of interior-wiring-system circuit elements is similar to that for an outside distribution system. The subject is treated in more detail in the author's "American Electricians' Handbook," page 109. The terms feeder, sub-feeder, main, sub-main, branch, tap, and distribution centre are defined diagramatically in the wiring layout shown in the lower part of the centre of Fig. 2. From inspection it is evident that these interior-wiring system elements can also be defined in essentially the same words as recited for the outside distribution system elements recited above.

Managing Committee

R. J. Beaumont, C. S. Bagg, A. A. Dion, D. H. McDougall, R. B. McDunnough, H. R. Mallison, W. H. McIntyre, J. F. Neild, J. S. Norris, L. W. Pratt, J. B. Woodyatt, the president of the National Electric Light Association.

Mr. John Melville, of Vancouver, B.C., says that semi-monthly POWER HOUSE is beneficial, especially to the engineer who is studying any particular course which may be in the issue—as a a month is too long to wait between articles.

Opportunity

THE Annual Convention of the C. A. S. E. this year held in Brantford is a thing of the past. It marks the close of a particularly strenuous four years in the life of the stationary engineer. Many of the features of war-time conventions were still noticeable and will exist for years to come. Economy in operation is still a most important feature and this phase of power plant operation was well exemplified in the various exhibits arranged by the Exhibitors' Association.

Economical plant equipment in itself will not ensure efficient operation and if the operating engineer wishes to keep abreast of the times and to bring the steam plant to such an efficiency as will meet the cheapness of outside power he will have to do a bit of self-improvement and must avail himself of the many opportunities offered for self-improvement.

It is to be regretted that more advantage is not taken of the educational features of conventions by the stationary engineers delegated thereto. Entertainment especially of a mediocre sort can never lend itself to personal advancement, while the exhibit shown by manufacturers are most excellent educational features and the technical papers presented form every valuable means of keeping abreast of the times, not only through the subject matter treated of but also through the opportunity for discussion presented. Indeed more is gained in discussion following after the reading of papers than in the papers themselves.

A New Prime Mover

ELSEWHERE in this issue is presented an account of a hybrid prime mover worthy of an engineering Burbank. By crossing a steam engine and an internal combustion engine a mechanism is produced for which very high efficiencies are claimed. It is a well-known fact that the internal combustion engine is one of the most efficient prime movers and that the majority of heat wasted goes into the jacket water. By using this heat for the production of steam and by using this steam on the underside of the piston an increased efficiency is obtained, a remarkable efficiency when compared with the older forms of heat engines.

The Still engine is perhaps as yet too little developed to hazard any guess as to its commercial feasibility, but should it come up to the expectations of its inventor, great changes can be expected particularly in the use of the internal combustion engine for ocean transport. Other applications will arise through the extreme flexibility of the mechanism and the powerful torque obtained at full loads.

The conserving of the world's fuel supply will render an invention such as this very attractive, the more so as the increasing cost of fuel will automatically force one to look around for cheaper and more efficient means of producing power.

Don't be a Tinker

DON'T be a tinker. If you are going to do anything in life, do it well.

Do one thing better than any person else can do it.

Ever see a handy-man? You know the kind. He's not particularly skilled at anything particular, but he can catch on quickly. He makes a great stop-gap in the shop—and he generally sticks right there.

Ever meet the chap who can play a few chords on the piano, and who can sing a couple of old songs to his own playing? He gets through all he knows in a few minutes, and if he has to do anything more, he's up against it. As a matter of fact, he's only a tinker. He can neither play nor sing, and yet he imagines he can do both.

You have seen the average clerk in operation in a store. No matter whether it's groceries, dry goods, boots and shoes. In a general way he can get you what you want if you have a pretty fair idea of what you want before you go in. But he will never sell you anything else. He will never size you up as you enter the store, or as he talks to you as a prospective customer for some new lines of goods that the store carries or is going to carry. He is just an average, garden variety. In fact, he's a tinker in his line of business.

Don't be a tinker. Do something, well—much better than any person else. Then there will be a demand for your services that will shove you head and shoulders past the tinker class.

The Millionth of an Inch

SOME folks is always hankerin' for to do some foolish thing, to say some startlin' statement or 'sassinate a king. They seem to have a mania for things what's strange and queer, you wouldn't think they had a brain tucked in behind their ear.

And then there's other things they do that seem to me most strange, they're clean beyond my vision, ten miles outside my range.

Now, take the chap what took an inch and carved the thing in two, I guess he thought that was a trick to puzzle me and you. And then some prune, he come along and split the thing in four, and them what watched the show that day they hollered out "encore!"

Well, time went on and bye-and-bye these choppers whacked away, until the chiefest of the lot rose up one day to say, "I've took that inch and by the use of hammers and of charts I've sliced the thing, by heck I have, into a thousand parts!"

Well, folks they donned their goggles for to see the bloomin' speck; it weren't no bigger than a hair what sprouts upon yer neck.

Well, not content with that there stunt, they started in once more, and sliced and rubbed that thousandth right down unto the core, until we read in words what make my fists go in a clinch, about there being in measurements the millionth of an inch.

Oh, I'd like to lay my husky hand upon that whiskered guy, who caused my head to swim about when I went out to spy, to gaze upon the millionth part of that there inch of ours, I've looked until my eyes most bust, I sweat for hours and hours.

I rise to say out good and loud so all your folks can hear, no matter if you dub me odd and just a trifle queer, "There ain't no such a thing about—to me that is a cinch —as that there atom that they call the millionth of an inch!"—ARK.

The Future of the File

A WELL-KNOWN Canadian firm, making files, has sent out word with its shipment that a file is a fine tool, and as such should be protected from rough usage. The notice even goes on to claim that better results can be secured from a well-preserved file.

As a matter of fact, this manufacturer is right, but we hate to believe him. The general acceptance is that a file is a utility tool, and that it can stand hard usage. Therefore, it is the duty of the man who gets a file to give it hard usage.

Ever use a file as a hammer? Not as a sledge, perhaps, but just as something handy at the time.

Ever pry the lids off cans with a file? Sure. Great thing for all such odd jobs.

Ever use the tang end of a file to dig a hole in a brick? Handy for this sort of work.

Ever turn over a heap of tools to find the file you want away at the bottom, where everything else in the box has had a chance to have a kick at it? Own up now, you have.

Most people have had about as much regard for a file as they have for a crow bar. Its cutting edge is regarded about the same as the family razor that shoots father's whiskers, pares mother's corns and when no person's looking sharpens the youngsters' lead pencils. The file is sort of a family instrument. Every house has one in the kitchen table drawer—that is every well-regulated household. And there are more hanged things done with and to that family file than ever happened in a bang-up three-ring circus. It pulls corks out of a bottle, it hammers tacks, it sits around on call when the carpet is being laid on the back stairs, and it comes into active service when the old man is wondering why under the sun the elbow from the kitchen range will not slide into the stove pipe hole like a reamed out cylinder and piston. It is the family file that crawls in beside that stubborn pipe and stays there too while the old man administers the final heave that puts the smoke stack in action.

Well, to be sure there may be better times on ahead for the file. It surely has had a whale of a time in its day, and when the day is over it generally gets its whiskers shaved off and does service as a screw driver, a chisel, a scraper, a centre punch, a drift or what not.

This process of education may do much. Certain if it does anything at all it must be for the better. It may even be that in years to come the file will get decent treatment in the shop and occupy, in the home, the place on the piano that is now given over to a picture of John Henry, taken in the suit he wore when sticking the point of a bayonet into the breeches of one Fritz.

OCCASIONALLY one sees a stork in the Zoo, but there must be a stack of these things some place in the woods, for there were 1,352,792 births in United States last year.

* * *

WHAT'S become of the shop joker who used to be sending the apprentice out to look for a left-hand monkey wrench and a flat-faced hammer?

* * *

A TRACTOR was being demonstrated at Richmond, Mich., when it became unmanageable and ran through a drug store. Being of the caterpillar type, there was doubtless something in the drug store to meet its case.

* * *

A CALIFORNIA man left $19,000 to his son. The only string is that the son has to earn $30,000 clear before he can get the $19,000. Chances are that by the time he piles up that sum he'll have cut enough wisdom teeth to know how to handle the smaller amount. It looks as though that fond parent knew a thing or two that the average chap never thinks about.

THE SLACKER B.T.U.

Behold the nimble B. T. U.
Now hastens toward the lofty flue;
He dances from the coal so black,
Around, across and up his track.
Along the furnace fiery walls
He dives and jumps, but never crawls;
Elusive, he, and small in size,
He's seldom seen by human eyes.
But hastening through the sooty tubes
In countless numbers—moves and moves
On through the baffles up and down
Against the shell so smooth and round,
Pushing and crowding here and there,
And mingling with the excess air,
Some holding back, a select few
Exclusive with the CO2,
To do their bit and turn to steam
The seething water, hot and clean.
But all the rest, now rushing, go
On through the breeching to and fro,
Pushing in haste to reach the stack,
A crowd of slackers, a lazy pack;
Up through the stack and to the air,
On, on they go; do we despair?
Ten thousand strong to every pound,
The work of ages in the ground;
Now and forevermore they're lost,
Into the great unknown they've crossed.
Quick! Plaster the brick work, close the cracks,
Change the draft, and raise the stack,
Level the fires, shovel the coal
A scoop at a time if you'd reach your goal,
And if it's too hard to think again,
Get a stoker that needs no brain,
Or the nimble heedless B. T. U.
Will prove much more than a match for you.

—Charles Brossman, in "The Combustion Chamber."

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Readers are invited to send in answers to these problems, as they have been chosen for their interest and application to the practical side of power plant operation.

Perhaps you, too, have some pet problems, or hard nuts which you would like to ask your fellow engineers; if so, send them along for the benefit of others.

Answers, together with the original question, will be published in the issues following the appearance of the question.

Questions Before the House

29.—Explain the purpose of the steam dome. (b) How are steam drums connected to the boiler and what provision is made in the latter case for expansion?

30.—Explain the purpose of the mud drum.

31.—What is the purpose of manholes, and how should they be placed so as not to weaken the shell unduly?

32.—How are steam domes attached to the boiler and what are the advantages of properly constructed dome bases?

33.—Explain the purpose of nozzles as applied to boilers?

34.—Explain the purpose of stays or braces.

Questions Answered

Question 24.—(a) Name the various forms of rivet heads used in boiler construction; (b) How are rivet heads formed? (c) In what respect has machine riveting advantages over other processes of riveting?

Answer.—(a) Countersunk head, button head, conoid head, oval head, flat head, oval countersunk head, cone head, and steeple head; (b) By hand, snap, pneumatic and machine riveting; (c) The pressure applied in machine riveting causes the shank of the rivet to upset thoroughly, thereby filling the hole completely, consequently a tighter joint is made than is possible with hand, snap, or pneumatic riveting.

Question 25. (a) What is a lap joint?; (b) What is a butt joint?; (c) Distinguish between single and double-riveted joints; (d) Distinguish between chain riveted and staggered riveted joints.

Answer.—(a) A joint formed by two plates that overlap each other and are joined together with one or more rows of rivets.

(b) A joint formed when two plates are placed edge to edge and are connected with covering straps.

(c) In a single riveted joint the force tending to tear the joints asunder is resisted by a single row of rivets, and in a double riveted joint by two rows of rivets.

(d) In chain riveting the rivets in the different rows are placed in line, in staggered riveting the rivets are placed zigzag.

* * *

Question 26—.Which is the strongest type of the ordinary riveted joints?

Answer.—The type of butt joint having double butt straps with the inner strap wider than the outer, and having part of the rivets in double shear and part in single shear.

* * *

Question 27. What precautions are taken in locating the longitudinal seams of externally fired boilers, and also of cylindrical furnace flues of internally fired boilers?

Answer.—In externally fired boilers care is taken to have the joints as far from the fire as possible; in cylindrical furnace flues the joint is placed just below the grates, where it is not exposed to the fire and does not interfere with cleaning the lower part of the flues.

* * *

Question 28. What objection can be urged against constructing the fire-door hole of a locomotive type boiler by flanging the inner and outer sheets to a single curve?

Answer.—Owing to the rigidity of the construction, the inner sheet is liable to crack in use, from the calking edge to the rivet holes and also in the curved part of the flange.

Readers' Queries

The Editor,—I beg to submit what appears a more practical solution of Question 11 than that appearing on page 167 of May 5 issue:

Area of piston, 452.39 sq. in.

Total pressure, $452.39 \times 100 = 45{,}239.$

Area in studs required $\frac{45{,}239}{5{,}000} = 9.05$ sq. in.

Assume 16 studs $\frac{9.05}{16} = .5656$ sq. in. per stud.

1 in. studs would be ⅞ in. at bottom of thread.

Area of ⅞ in dia. = .6013 sq. in., which is a little stronger than required.

Regarding pitch circle. I would make it 27½ in. diameter, which would allow a full inch between counter bore and studs.

Pitch of studs to be 5.4 in.

W. C.

WHO IS BLIND?

Will every person who reads this notice, and knows a blind man or woman anywhere in Canada. kindly send the name and address of that blind one to the Canadian National Institute for the Blind, 36 King St. East, Toronto.

The institute is conducting work for the blind along the most modern scientific lines and desires that each blind resident of Canada should have the opportunity of availing himself or herself of the benefits represented by this work.

The immense task of registering every case of blindness can only be accomplished successfully by the earnest cooperation of the public generally. That is why we ask you to send the names and addresses of blind people you may know.

The following departments of work are being actively prosecuted by the institute:

Industrial Department for Men.
Industrial Department for Women.
Department of Field Work.
Department of Home Teaching.
Department of Prevention of Blindness.
Library Department.
Department of After Care.
Residence and Vocational Training Centre for Blinded Soldiers.

To send information or obtain information, address the General Secretary, Canadian National Institute for the Blind, 36 King St. East, Toronto.

Progress in New Equipment

THE RILEY TWO-SPEED GEAR BOX

THE Riley two-speed gear box differs from stoker gear boxes in that it contains in addition to the worm gearing a double set of spur gears. These gears are so arranged in the bottom of the gear box that by shifting the lever from high to low speed position, or vice versa, the coal feed may be retarded or accelerated. It means that on large units the fire can be levelled, thinned, or thickened as required.

When a number of stokers or gear boxes are driven by a single prime mover, any stoker or the retorts on any gear box can be operated practically independently of all other stokers or gear boxes. This effects a saving in fuel, since there is no necessity for carrying over coke when trying to divide the load equally among a number of stokers. or when building up thin sections of the fuel bed in a wide furnace.

With the stokers driven by an ordinary engine or motor, double the usual range of speed is obtained. This is an advantage at high ratings (300 to 350 per cent.). The stoker counter-shaft at these loads usually has a speed of from 400-450 r.p.m. Suppose, for example, the load is suddenly reduced to about rating on the boilers; an engine to handle this would need to operate from 100 to 150 r.p.m. Such low speeds are not only liable to stall the engine but are extremely wasteful of steam. Shift the two-speed gear box lever from high to low speed and the engine can operate from 200 to 300 r.p.m., an efficient speed for economical operation.

The installation of the two-speed gear box makes the slip ring induction motor more suitable for stoker drive. A 2 to 1 reduction in speed is all that can be obtained electrically, but with this new device an over-all range of speed of 4 to 1 is obtained. A multi-speed motor with four speeds, 600, 900, 1,200 and 1,800 r.p.m. can now give the equivalent of 300, 450, 600, 900, 1,200, and 1,800 r.p.m. If the motor operates at a maximum of 1,800 r.p.m. during peaks—then a sudden change in steam requirements does not necessitate feeding an excess amount of coal to the boiler. A single throw of the shifter lever from left to right cuts the coal supply in half. This is done without a change in the speed of the motor.

FIG. 2—CROSS-SECTION THROUGH RILEY UNDERFEED STOKER SHOWING THE OPERATION OF THE TWO-SPEED GEAR BOX.

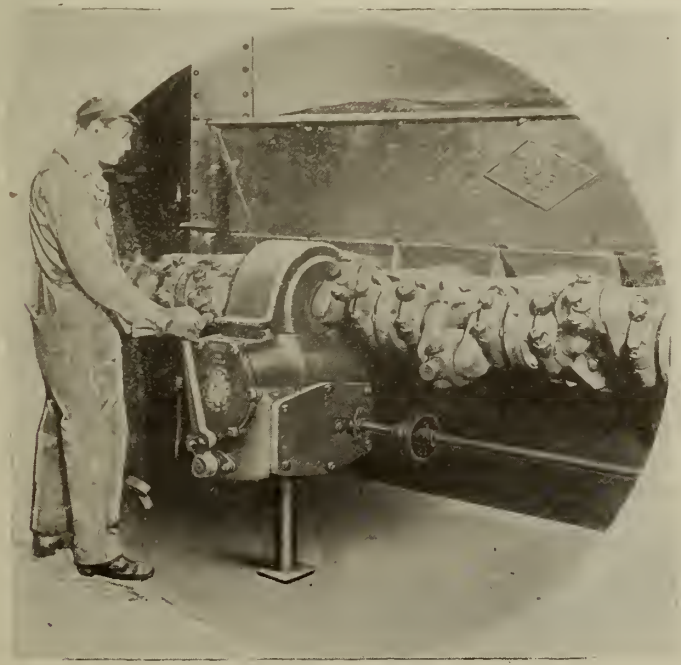

FIG. 1—RILEY TWO-SPEED GEAR BOX AS APPLIED TO 14-RETORT RILEY STOKER AT THE WORCESTER ELECTRIC LIGHT COMPANY, WORCESTER, MASS.

The illustrations shown in Figs. 1, 2 and 3 show the simplicity of an installation. The makers call attention to Fig. 3 and point out how all gear boxes are driven from one through shaft. It is therefore obvious that all sprockets and chain connections, chain guards, countershafts and bearings usually required for each gear box are eliminated. Each stoker with the new Riley two-speed gear box has but one chain connection. With large units this saves a great deal of mechanism underneath the stoker.

At the Camden plant of the Public Service Electric Co., of New Jersey, it was found that by using the two-speed gear box the stokers could be set much lower. In fact the bottom of the box can be set directly on the floor. This is an economical advantage with low set boilers, since it enables the stoker to be set low, giving maximum space for the gases.

The use of this additional regulating feature does not interfere in any way with the continued use of any automatic regulating device; in fact, it allows a more intelligent use of any automatic regulator on the stoker drive.

The Riley two-speed gear box is so constructed that it may be applied to

any type of Riley stoker. It is manufactured by the Sanford Riley Stoker Company of Worcester, Mass.

LEAD BURNING TRANSFORMER

The most modern method of burning terminals in place on storage batteries, removing old connections, cutting off or building up posts, or in fact almost

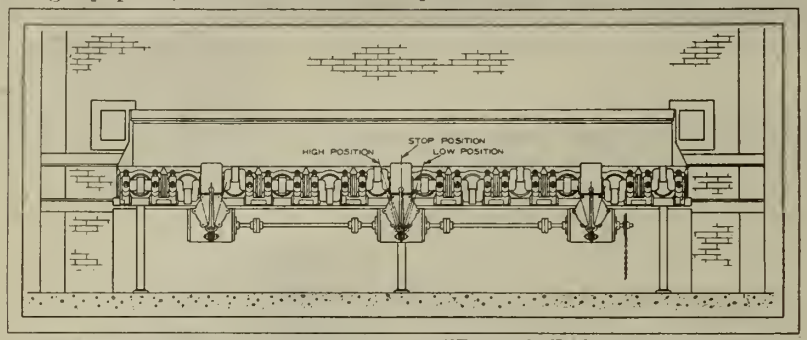

FIG. 3—FRONT ELEVATION OF 12-RETORT STOKER SHOWING THREE 2-SPEED BOXES. NOTE THE CONTINUOUS LINESHAFT UNDERNEATH THE STOKER AND THAT THERE IS ONLY ONE CHAIN CONNECTION PER STOKER.

any form of lead work, is to do it electrically—by the electric welding process.

The General Electric Company has recently developed a lead burning transformer to meet this need, an illustration of which is shown herewith.

This transformer is designed to be connected to the ordinary 110 volt alternating current lamp socket, a 10-foot cord with plug being provided for this purpose. This attaching cord is protected by a special rubber covering against the hard wear, dirt and acid with which it may come in contact. Connection to the transformer itself is made by means of a plug and socket connection so that this plug can be used in place of the snap-switch in the lamp socket for turning the current on and off.

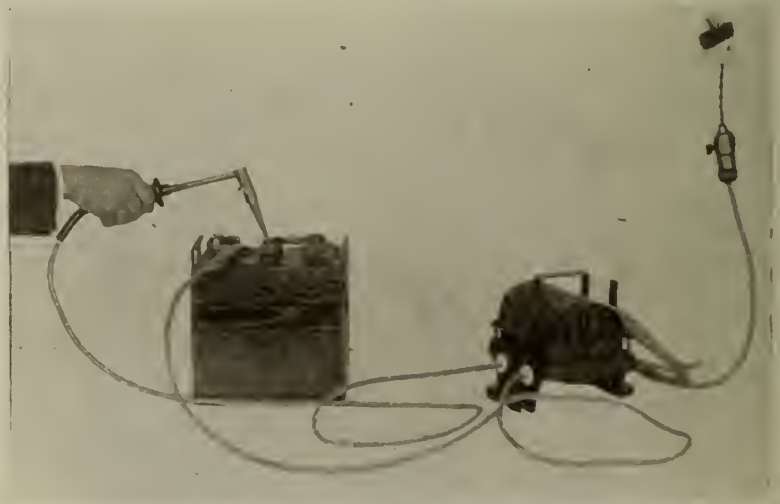
Two separate rubber-covered terminal leads are used to convey the low voltage heat producing current to the parts of the battery to be welded (see illustration). The lead having the "Big Brute" clip is for fastening to the battery plate or posts which is to be worked on. The other lead has at its end a carbon holder which is arranged with a heavily insulated handle so that the operator's hand is guarded from the heat. The carbon holder takes any ordinary arc welding carbon, this carbon forming the second terminal.

When the pointed arc welding carbon is brought into contact with the lead the pointed end of the carbon becomes intensely hot, so hot that it melts the lead over a restricted area quicker than a pointed gas flame will do it. The welding or burning operation is carried out by a sort of pudding process, the carbon terminal being manipulated to flow the lead where it is needed.

Among the advantages of the electric lead burner, is that repair work in hard-to-get-at corners can be done more easily as the heat is always right at the point of the carbon, the device is readily portable, weighing approximately 25 pounds; joints do not have to be developed by the Westinghouse Electric cleaned as the dirt and slag automatically rise to the surface of the molten lead and the surfaces are joined while cleansed; when properly used, there is no glare to injure the operator's eyes, as he looks down on the cool end of the carbon in such a way that the bright point where the carbon touches the lead is hidden from view; there is no danger from electric shock because of efficient insulation.

On the basis of 10 cents per kilowatt hour, it costs about 8 cents per hour for current when the device is operating steadily. The instant the carbon point is removed from the work, the current consumption practically ceases as the device then takes only 4½ watts from the line.

Owners of these transformers have found an increasing field of application. The device is said to be especially valuable to automobile owners in reconstructing and repairing batteries; while in the shop and foundry it has been used where all kinds of odd soldering jobs must be done. The device has also been found applicable in plumbing, roofing, tank building, etc.



SHOWING THE USE OF THE LEAD BURNING TRANSFORMER IN BURNING THE POSTS ON A STORAGE BATTERY.

METERS FOR WIRELESS AND HIGH-FREQUENCY WORK

A high grade hot-wire measuring instrument designed particularly for wireless and other high-frequency work, depending for its operation upon the expansion of a metal strip which is heated by the current to be measured has been brought out. The slight sag in this conducting strip is magnified several hundred times on the scale by means of a combination of wires and a deflecting spring.

The conducting strip is made of special non-corrosive material. The separating posts have the same temperature coefficient of expansion as the conducting strip, so that the changes in room temperature do not cause an error in the reading of the instrument.

The instruments are furnished in two forms, for flush mounting and portable. Similar instruments for switchboard mounting are supplied.

The flush-mounting form, known as type EH, is of the round open-face type; the face is 3 inches in diameter and the diameter outside the flange is 3¾ inches. It has a black rubberoid case and rim, with white dial.

The portable form, known as type PH, is mounted in a morocco leather covered wooden case with heavy glass over the dial. The case is 3¾ by 4⅜ inches by 2 inches thick.

The scale plate is made of metal, and the scale subtends an arc of 90 degrees, being 2⅜ inches long.

METER FOR HIGH FREQUENCY WORK.

The type EH meters have a guaranteed accuracy of 2 per cent., while the type PH, with hand-marked scale, can be expected to show an accuracy within 1 per cent. of full scale. Standard meters are for 1, 2 and 5 amperes. Care must be used not to subject the instrument to more than 200 per cent. load.

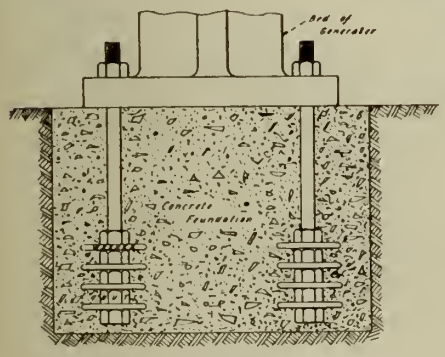
The Operators' Point of View

ANCHORING FOUNDATION BOLTS IN CONCRETE

By TERRELL CROFT

THE effectiveness of the adhesion between an iron rod and the concrete in which the rod is embedded does not appear to be appreciated by many men who instal concrete foundations for machinery. For example, the arrangement shown was used in a certain instance to provide an anchor for the foundation bolts of a machine. The series of nuts and washers on the lower ends of the bolts was entirely unnecessary, as will be demonstrated.

The maximum adhesion between a round iron rod and concrete amounts to between 250 and 400 lb. per sq. in. of contact area. A safe value for this adhesion may be taken as 75 lb. per sq. in. These values have been verified many times by actual tests. Working from these data, it can be shown that if a round iron rod is embedded in concrete to a depth equal to 30 times its diameter the rod will break before it pulls from the cement, if force is applied to effect its withdrawal. Therefore, if a 1-in. diameter foundation bolt with its surface perfectly smooth be set in concrete for a depth of 30 in., the rod will break before it can be pulled loose from the concrete. Roughening the rod by threading it or by chipping or by cutting fins in it has very little effect, one way or the other. However, as a matter of precaution it is always well to use for a foundation bolt a rod threaded and having a nut on the lower end. On this nut a cast iron building washer or a square piece of wrought-iron plate can rest, which will insure against withdrawal if the bolt is not set 30 times its diameter in the concrete.



ANCHORING FOUNDATION BOLTS IN CONCRETE.

ONE METHOD OF COLORING INCANDESCENT LAMPS

By J. C. Lupton

(Copyright. All rights reserved).

The lamps may be connected in a circuit with the current turned on so that the filament is at its usual brightness. Then they are dipped in white shellac, thinned with alcohol. This shellac coating will give the lamps the appearance of frosted glass. The current should be going through the lamps while they are being dipped so that the shellac will dry quickly and not run. If different colors are desired, such as red, blue, green and the like, dyes or pigments of the required shades can be mixed in the shellac in which the lamp is dipped. This is not necessarily the method which is used in lamp factories, but in practice it has been found very satisfactory.

HOW AN ELECTRICAL MACHINE IS RATED

By Clarence L. Fleet

The universal practice in rating all electrical apparatus is to rate it on the basis of its electrical output. That is, the name plates on generators, motors, transformers, and the like indicate the safe output capacities of the equipment. Motors have, in the past, been rated on the basis of their h.p. outputs, but the best practice now dictates that they should be rated on the basis of their kilowatts output.

ION AND IONIZATION

By Alfred Long

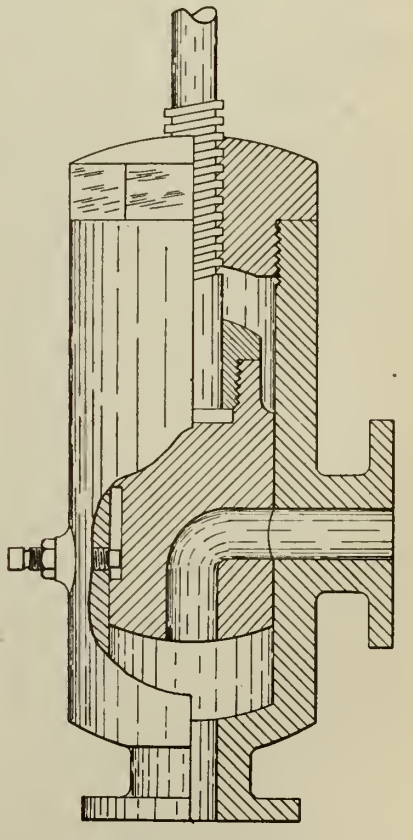
(Copyright. All rights reserved).

The terms "ion" and "ionization" are now used frequently in electrical literature. There are really two kinds of ionization; first, the ionization of solutions or electrolytes, and, second, the ionization of gaseous substances, like air, for example. In an electrolyte, an ion is one of the electrified particles into which a molecule is supposed to divide in a solution. In a gas, an ion is one of the small electrified particles into which the molecules of a gas may be broken up under certain conditions. In general, then, ionization is the breaking apart of the molecules of a substance into positively and negatively-charged particles.

ANGULAR BLOW-OFF SUGGESTION

By K. Walsh

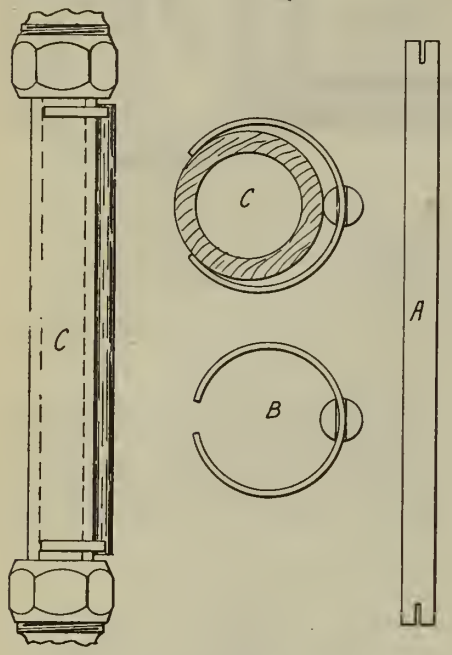
The accompanying sketch illustrates the angle type of blow-off valve of the design shown in the April 5th issue of the POWER HOUSE. It will be noted that the plunger that forms the valve is cored out to divert the flow at right angles. The port is closed by lowering the valve spindle, which is held to the plunger by the retaining nut shown. The plunger is close fitting so that packing the stem is unnecessary, and by its construction scale troubles are eliminated. To prevent the plunger turning in the valve body, it is guided in its movement by the screw on the left, the point operating in a slot cut in the plunger opposite to the cored passage.



BLOW-OFF VALVE.

IMPROVING THE WATER GAUGE

I have a gauge glass in a location where the water level is not easily discernible and after trying several suggested stunts for making it plain,



ATTACHMENT FOR GAUGE GLASS

I have evolved one of my own, which, in my case at least, beats them all.

Take a piece of steel rod about ¼ inch in diameter, smooth and straight and of a length that will be up against the side of the glass and not pinch between the packing nut. Hack-saw slots in each end of it as at A, and into these slots insert a loop of steel spring cut from a window-shade roller, as at B, fastening them by pinching up the slots with hammer or vise. Take a ribbon of emery cloth and saw it about the rod unitl it is highly polished and then attach it to the glass as at C and C. The rod will lie tight against the glass directly opposite the viewpoint; and with an electric light in front of the glass the water will look like milk. This device can be snapped on and off instantly for cleaning of the glass or rod; and can be swung about the glass to face any direction for best results from the viewpoint.

R. MANLY ORR.

FLYWHEEL DATA

By J. G. Noble

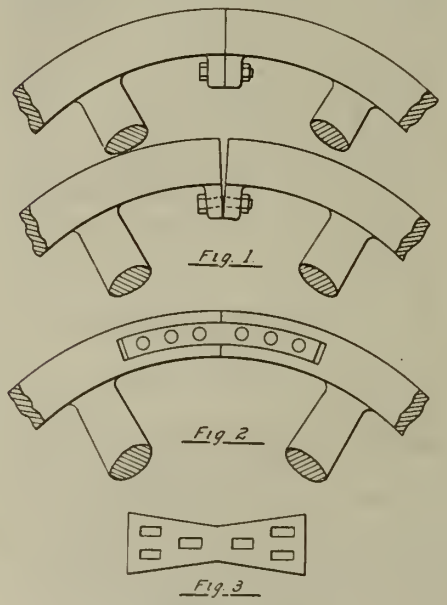
A great deal of information is written about steam boiler explosions, even when no explosions are taking place. Seldom, however, do we see any quantity of printed information about flywheel wrecks, unless it be some description of a recent accident. A simple explanation of this kind of a smash-up was given some time ago in a London paper somewhat as follows:

The tension upon the rim of a revolving wheel augments as the square of the velocity—that is to say, supposing for the moment that we had a wheel with a rim a foot square, revolving at the rate of 100 feet per second, the material being cast iron—the total resolved forces tending to tear the rim asunder would be, say, 144,000 pounds.

Now, imagine this velocity to be increased by the failure of the governor to act, or otherwise, to 150 (feet per second, or one and a half times as fast as before—a perfectly possible case—and we have 324,000 pounds to deal with. Double the original speed and we have 576,000 pounds.

Supposing the wheel to break up under the stress due to the last-named speed, 200 feet per second, there is energy resident in that rim sufficient to throw any part of it which might happen to be tossed vertically, 600 feet into the air.

This will give some idea of the potential force lying dormant in a flywheel. Perhaps some readers will remark: Well, there is nothing new to us in these London paper extracts; maybe not, but still engineers will block their engine stops



FLYWHEEL DATA.

when they get out of order instead of having them put right.

There is just as much danger in a faulty engine governor as there is in a leaky steam boiler. The day will come when it will be compulsory to have the engine governor and flywheel examined by a trained inspector, employed by the insurance companies, as steam boilers now are.

The bursting speed of a solid cast iron rim, that is with no joints, is about 425 feet per second.

Many flywheels, even the smaller sizes, are built up in sections, especially is this so in many of the old machines.

I remember seeing one, years ago, with internal flanges as shown in Fig. 1; of course the centrifugal force tends to open the joints in such a wheel as shown in the sketch. In thin rim wheels bolted together in this manner the stress would be much less than in the thick or deep rim wheel. A much better way to clamp a deep rim wheel is shown in Fig. 2, one of these clamps being at each side of a joint. A clamp in the form shown in Fig. 3 has been used, the piece fitting into a space of the same shape on the wheel rim. Every joint on a flywheel should be placed as near as practicable to one of the wheel arms.

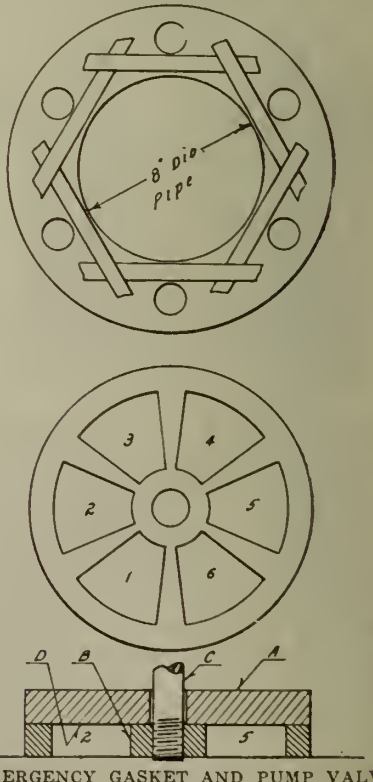
WHICH ARE BEST: PLUGS OR CAPS?

I notice that J. E. McCormack, on page 233, June POWER HOUSE, tells the poor engineer that a cap is better than a coupling and a plug. Sure, J. E., right you are. But what about the rest of it? It is just as easy to remove a coupling as it is to remove a cap, and it is often necessary to put a thread on a piece of iron rod and saw off the end, to use when there are neither caps nor plugs on hand. Anyhow, do not burn or scald your fingers removing a plug; unscrew the coupling.

JIMMIE JAMES.

A POWER PLANT KINK AND A QUESTION

The sketch, Fig. 1, shows how one man overcame a problem. He had a joint to make on an eight inch pipe flange and only had a few scraps of sheet packing. However, he succeeded in getting a few narrow strips from the scraps and put them to use as shown. After the bolt



EMERGENCY GASKET AND PUMP VALVE PROBLEM.

nuts were drawn tight the steam pressure was turned on slowly and the nuts followed up; the steam pressure carried was 100 pounds gauge. The reason for following up on the bolts is on account

of the laps on the rubber strips, where they cross each other. On Fig. 2, A is a pump valve, rubber, brass, or any other material. B is the valve seat, and C is the bolt.

If the pump is delivering water at 100 pounds pressure per square inch, that will be the pressure on the top of A. Also there is likely to be the pressure of a spring.

The area at D will only be equal to the openings at 1, 2, 3, 4, 5, 6. If there is a pressure gauge above the valve and one below, it will then show a difference in pressure until the valve lifts from the seat.

My only reason for writing the foregoing is because I have never noticed the matter in print or heard it discussed, and I thought it might prove of interest.

JOHN THORN.

FIXING THE OIL FEED

Occasionally the engineer has a somewhat large bunch of things happen to try his temper or his patience, one of the least of these is the tendency of the oil feed from a lubricator tube slumping over in a careless, don't give a hang if I do work style, and taking a grip on the inside of the sight feed glass. gradually covering it over until as an indicator it is "nix." Numerous remedies have been suggested, by correspondents, to overcome this trouble, such as soldering one or more wires to the bottom feed tube to guide the oil drops to the outlet at the top of the glass, or soldering a wire to the inside of the plug at the top of the glas, allowing it to extend down to near the opening of the feed tube, so that the oil drop will touch it and therefore follow it to the top. Another suggestion is to make a small groove with a fine file around, and close to, the top of the oil feed tube, the idea being that it will have a tenddency to hold the oil until the drop forms large enough to take its upward trip. However. some oils are so "doped," or artificially thickened that any of these schemes might prove ineffective. One idea which has given fine results is as follows:

Carefully clean the inside of the sight feed glass. Next take a mixture of one part water and three parts glycerine and fill the glass with it.

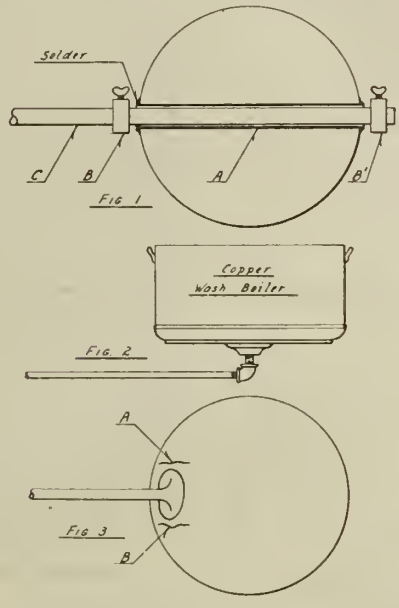
I have never heard a kick from any engineer who used this plan.

Glycerine has a specific gravity of about 1.26 with water 1—this will cause the oil to travel somewhat slower than if water alone is used, but the oil feed can be cut down to a "snail's pace," but the oil feed will remain positive no matter how low the cut. This is a big improvement over the water, as, when the feed is very slow in the latter case it has a bad habit of stopping altogether.

JAMES ELLETHORN.

REPAIRING COPPER FLOATS

In large water tanks supplied from city mains or private pumping outfits there is usually a ball cock on the outlet end of the feed pipe in the tank. These cocks are controlled by a copper float varying in diameter from 10 inches



to 20 inches; usually the floats are of light sheet copper, and very often they crack or tear open at A and B, Fig. 3. One engineer got free from this trouble by using an ordinary copper wash boiler as in Fig. 2. The old float was about beyond repair and there was no new float in the town's supply house. By connecting the lever to the bottom of the boiler the force of the lift was distributed over a large surface. By connecting the lever on a ball float in the same way it will give it a longer life. One way used often is shown in Fig. 7. A piece of tube, A, is run through the ball and soldered at the ends; the lever C is run through the tube and held in position by the thumbscrews and collars B B'. Sometimes the lever is run through the ball and soldered at each side and the tube dispensed with.

J. JAMES.

POWER PLANTS

It would be difficult to find an engineering subject better calculated to set the controversial ball a-rolling than that of the comparative working costs of the principal types of prime movers; and Mr Oswald Wans, in reading his paper on the subject before the Institution of Mechanical Engineers of Great Britain was, no doubt, fully prepared for the animated and even contentious discussion that followed. As was only to be expected, faults were found with some of his assumptions, and not a few of figures were challenged by members connected with firms specializing on engines of particular types. Yet the central proposition of his paper —that commercial advantage, not technical superiority, is the ultimate criterion of an engine's worth—was not for a moment in dispute. It is, of course, a truism, but it is none the less worth reasserting from time to time. The right choice of prime mover depends upon the correct balancing of innumerable factors which vary according to time, place, conditions, and particular power requirements. To say that a certain type of engine possesses a high thermal efficiency does not necessarily establish its superiority. That is one factor, it may be overcome by a dozen others. The total working cost of a powerful plant is compounded of capital charges in the shape of depreciation, insurance and interest, and of running charges in the shape of fuel, lubricating oil, water supply, sundry stores, labor and repairs, and before one can say which is the best type of power plant for a particular purpose all these factors have to be taken into account. The object of Mr. Wans was to give data likely to be of service in estimating capital expenditures and working costs, and in establishing the relative commercial value of the principal prime movers. For this purpose he took typical examples of the five types of prime movers—suction-gas engines, and plants burning anthracite, coke and wood refuse; gas engines of the solid injection, high-compression type; Diesel engines, and steam engines, and reduced a mass of information, the collection and analysis of which must have entailed great labor, to a series of comparative curves plotted for each item of capital and running expenditure. The conclusions to be drawn from these curves are useful, though fairly commonplace. Thermal efficiency has its importance, but the overruling factor is the relative prices of fuel in the locality. The advantage of the steam engine rests largely on cheap coal. If the price of coal exceeds on the average one-fifth the price of fuel oil the advantage passes to the solid injection oil engine; if it exceeds one-fourth the price of fuel oil the Diesel engine comes into effective competition. This is for engines of 250 h.p. and over; for smaller plants coal must be relatively cheaper still. Between these extremes stands the suction-gas plant, for which the prices of coal and coke may be respectively twice and 1½ times the price of coal for steam engines of the larger powers. The use of town gas engines is clearly confined to the few cities in which gas can be obtained at about 1s. 1d. per 1,000 cu. ft., and the refuse section-gas installations to industries in which there is an ample supply of suitable waste material. In relegating thermal efficiency to its proper place in the scale of factors, Mr. Wans passed over one very relevant matter; that the importance of thermal efficiency increases with every rise in the cost of fuels generally, and the value of his paper would have been enhanced if he had added to the excellent series

of plotted curves one illustrating this tendency.

In comparing the rival merits of the leading types of engines, Mr. Wans gives prominence to a point which, though it greatly affects capital expenditure, fuel economy, and reliability, often receives far too little consideration—that of over-load capacity. For every engine there is a load at which the engine works at its highest efficiency. That is the rated working load. But it adds greatly to the utility of an engine if it can be made, at a pinch, to carry a considerably higher load. In this respect the steam engine shows an elasticity far greater than any of its competitors. as the following figures for the maximum over-load that can be relied upon with different types of engines shows:

Installation.	Percentage of Mean Working Load Below Rated Working Load	Increase in Consumption due to Underloading.
Steam	Nil	Nil
Oil engine	14.5	2.5
Diesel engine	14.5	2.5
Suction-gas engine	18.5	12.0
Town-gas engine	18.5	8.0

The effect of this upon capital expenditure where fluctuating and peak loads have to be reckoned with is apparent. Take the case of an engine required to work at a mean load of 100 b.h.p., but to be capable of meeting an occasional demand for 135 h.p. In such a case a steam engine of 100 b.h.p. rated working load would answer the requirements, but if a gas or oil engine were being installed, a gas engine rated at 123 b.h.p. or an oil engine rated at 117 b.h.p. would be required to meet the overload demand of 135 b.h.p. Thus a larger engine would be needed, and the initial capital cost would be large in proportion. But even more important would be the effect on fuel economy. At the mean load of 100 b.h.p. the steam engine would be working at its maximum efficiency, whereas the gas or oil engine would be working under load, and, consequently, at a reduced efficiency. The following table shows the increase in fuel consumption due to the underloading necessitated by an overload of 35 per cent.:

Steam engine	35 per cent. above rated working load
Solid injection oil engine	15 per cent. above rated working load
Diesel engine	15 per cent. above rated working load
Gas engine	10 per cent. above rated working load

A further allowance must be made for stand-by losses, which will depend upon the frequency and length of the stoppages. The loss, of course, applies only to suction gas and steam installations, and the amount may vary considerably according to the care exercised.

CERAMIC ENGINEERING

Interest in the subject of refractory materials has been growing very considerably recently, and important developments may shortly be expected. There is a movement on foot to start a refractories society, or to inaugurate a joint refractories committee of the societies and institutions interested, possibly on lines similar to those adopted in the case of the Engineering Standards Committee; whilst another proposition is that to the existing Ceramic Society there should be attached a section dealing with refractory materials.

As regards the latter suggestion, the idea appears to be that the papers read before the refractory section would be published in the transactions of the Ceramic Society, the latter thereby coming to rival in utility the similar German society known as the Verein Deutscher Fabriken Feuerfester Produkte. It appears to be doubtful, however, whether the existing metallurgical institutions which are so closely associated with the use of refractory materials, would be willing to see their interests in this connection taken charge of by a society which has hitherto dealt practically entirely with the question of pottery clays, and has not particularly identified itself with refractory materials as they are understood by engineers and metallurgists.

It ought to be carefully borne in mind, however, by those who are inclined to throw cold water upon any possible extension of the Ceramic Society or on the proposal to form a new organization to deal with refractories, that the subjects to be covered are increasing daily in importance as the war progresses, and that after the war they will be still more important in Great Britain.

In the United States of America so vital are the ceramic industries held to be that the University of Illinois has just spent over £100,000 on a department of ceramic engineering, the buildings of which were formally opened recently. The occasion was one of great interest to the clay workers in the United States and the opening ceremonies were attended by many representatives of the architectural, structural, mining, geological, chemical and manufacturing interests. In connection with the inaugural ceremonies an industrial conference was held, in which a number of topics of current interest to the ceramic engineer, the clay worker, and the manufacturer were discussed by well-known experts. Already the number of students entered for the course of ceramic engineering in the University of Illinois is forty-six, which would appear to be a very satisfactory figure wherewith to inaugurate a totally new branch of university study, one of which more is bound to be heard of also on this side of the Atlantic.

When comparing the merits of refractories diatomaceous brick and slag wool, it has been assumed that the temperatures afforded a relative measure of the efficiencies of these two materials from the standpoint of thermal insulation, instead of which they were given merely to indicate the range of temperature over which experiments were made. Owing to the various other factors involved, the figures which have been published from time to time did not give a direct indication of the relative merits of diatomaceous brick and slag wool. If the two samples had been of exactly the same thickness and the cold faces had been allowed to radiate freely, the deductions would have been quite legitimate. In the experiments, however, it was desired to determine the heat transmitted in absolute measure, consequently a calorimeter was cemented on the cold face. A comparison between the two materials may be effected by means of the data in the table given below:

Mean Temperature of hot and cold faces.	Diatomaceous bricks.	Slag wool mats
300 deg. Fah.	0.92	0.48
600 deg. Fah.	0.11	0.72
900 deg. Fah.	1.31	0.96

* The thermal conductivity is the heat transmitted in B.Th.U.'s per sq. ft. per hour per lin. thickness for 1 deg. Fah. difference of temperature between the faces.

Of these materials which were chosen as illustrative of two distinct classes, the one a solid brick, the other a compressible packing material, it is indicated quite clearly above that slag wool —an entirely British invention and product—is really the better heat insulator.

BOOK REVIEWS

"Automobile and Aero Engines," by Rene Devillers, translated by Wm. John Walker, E. and F. N. Spon, Ltd., London and New York. Price 16/10.

Industrial progress and technical literature follow closely parallel lines,

Western Association of Mechanical and Electrical Engineers

Edmonton District Loop No. 5

This Association would be pleased to receive correspondence from any engineers who would like to associate with us with a view of getting better conditions for the craft in general. We would also be pleased to have communications from any other society or societies of engineers who are endeavoring to secure these conditions. Address all communications to

The Secretary,
Western Association of Mechanical and Electrical Engineers.
P.O. Box 991, Edmonton, Alberta, Canada

and where marked progress has been made in any branch of science it is necessary that recent knowledge gained by the few should be widely disseminated if stagnation is not to result. The war has witnessed a phenomenal advance in the theory and construction of the internal combustion engine as applied to land and aerial transport, and the author of the present work has achieved a high degree of success in the arrangement and choice of his material and in the bringing of the technical literature of the subject up to date. It may be mentioned at the outset that the work is not a mere collection of half-tone engravings and descriptive matter but is a well thought out treatise on actual design. Mathematics is necessarily called into extensive play, and indeed forms the groundwork of the whole structure. Much of the analysis comprised within the pages of this volume has as yet received little or no attention in any published textbook or periodical dealing with the subject, due, no doubt, to the restrictions placed upon such publications by war conditions. Calculus has necessarily been introduced into the many formulæ, but the treatment is exceptionally clear and lucid. Particular attention is drawn to Chapters IV, XII, XXIII and XXIV. The first two, on the subjects of inertia forces and cams respectively, are dealt with in a manner which compel admiration for the author's lucidity of exposition. The expressions obtained in Chapter IV for piston velocities and accelerations although not new, are elegantly obtained and their connection with the corresponding expressions for the Desaxee engine, given in Chapter X are readily apparent. Chapter XXIII deals with the adaptability of power available to the power required for aeroplane sustentation and propulsion. This, besides opening up in excellent fashion

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

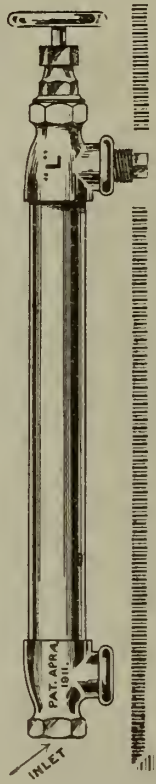
Use The LONG for STEAM TRAP SATISFACTION



Automatically drains jacket kettles, separators, steam mains. Works against 1 to 200 pounds pressure. Has two outlets and is installed in any position. DOESN'T FREEZE.
The Hamilton Powder Works, Beloeil, P.Q., use them with great success. Read this letter: Dear Sir: We have used one of your steam traps for a long time and have found the same to answer the purpose as well as any seen in operation. We were so pleased with the working of this steam trap last winter that we ordered six more this season and have fitted them up at various points in the works where live steam is used for heating purposes.
(Signed) J. Murray Wilson, Superintendent
Our trap will give you the same satisfaction as recorded above. Investigate and you'll be satisfied, too.

a comparatively new field for future investigation, is interesting as a record of recent progress made in France in the economics of aeroplane power supply.

In Chapter XXIV, on the principles of super compression and super charging, analysis of these problems are given which will appeal strongly to the student interested in such matters. All French units have been transformed into the corresponding English units. For those wishing a sound and intimate knowledge of the design features of aero and automobile engine design the book is commended. The following gives a synopsis of chapters not mentioned above: The Working Mixture—The Laws of Gases and Their Application to the Working Mixture—The Four-Stroke Cycle—The Engine Turning Moment—The Cylinder—The Piston, Piston Rings, and Gudgeon Pin—The Connecting Rod—The Crank Shaft—Valves and Cam Distributor Gear—Induction and Exhaust Passages—Engine Power and its Variations—The Cooling System—The Crank Case and Lubricating System—Speed Regulation—Engine Starting—The Two-Stroke Engine—The Rotary Engine—The Laws of Similarity—Engine Testing and three Appendices, giving derivation of formulæ and table of atmospheric constants.

TRADE GOSSIP

Leather Prices High.—Owing to the depletion of stocks of tanners in Canada, caused by the lifting of the British embargo to Canada, while the American embargo continued, prices have advanced materially. Tanners are exercising extreme caution, as they feel that the high prices may come down materially during the next few months, and are, therefore, unwilling to speculate on the future values. They are, therefore, keeping operations down, and this combined with the scarcity of raw materials, tends to keep the prices firm at their present levels.

Business Change — The Monash line of pressure reducing valves and pump governors, formerly manufactured and sold by the Monash-Younker Co., of New York and Chicago, has been acquired by the Harrison Safety Boiler Works, of Philadelphia. The purchase includes a stock of manufactured parts and valves, drawings, patterns, trade mark, and goodwill. The Harrison Safety Boiler Works will manufacture and market the valves under the trade name "Cochrane-Monash," and will supply repair parts for valves now in use.

His many friends throughout the country were grieved to learn of the death at St. Michael's Hospital of J. Frank Brown, following an operation for appendicitis. Deceased was the second son of J. F. Brown, 143 Dowling avenue, Toronto, was 21 years of age, and before enlisting with the 1st Tank Battalion was metallurgist chemist at his father's plant. Brown's Copper & Brass Rolling Mills, New Toronto. He received his education in the Separate and Technical Schools, was well known in athletic circles, and was an accomplished musician.

Large Foreign Order.—Armstrong, Whitworth of Canada, Ltd., with works at Longueuil, Quebec, have just completed one of the largest individual orders for steel tires placed this year, covering 3,000 tires, placed by the Netherlands Government, New York office, for shipment to the Dutch Indies. These tires were manufactured from raw materials at this company's works at Longueuil. The steel was made in Heroult electric furnaces, and the tires were manufactured with the equipment installed early in 1918 when the tire and wheel plant was added to the present works at Longueuil. This is a concrete example of what Canadian manufacturers can do to secure foreign trade, and the success with which this order was handled by this company has acted as an impetus to further developing foreign trade. Needless to say, the Netherlands Government assured themselves of the very high quality of steel tires which this company are making before placing the order in their hands, and it should be a source of gratification to Canadian manufacturers to know that markets heretofore controlled by Germany can be secured.

A New Alloy.—It is reported that a new alloy has been discovered that is lighter than aluminum. The alloy is being used in the manufacture of airplane piston rods for the Italian army planes by a firm in the Province of Quebec.

Your Plant's Record Is Your Record

The engineer must stand upon the record of what he saves—not what he produces. He can turn his job into productive instead of "non-productive" work (as it appears on the payroll) by producing economies that are the same as **profits.**

Primarily the plant and the man running it are gauged by this simple test:

How much steam is produced per pound of coal burned, and how much power is produced by that steam?

One simple, but versatile instrument enables you to determine this and trace all the errors that dwarf boiler output—the

Republic Flow Meter

Connected to individual boilers it shows at which capacity highest efficiency is obtained. It enables you to equalize the load between various units and guards against the extravagant condition of one boiler lagging while others are being crowded to high overrating.

Connected to the steam line it shows which departments are consuming the proper amount of steam and offers a basis for correcting errors and pro-rating power costs.

The Republic Flow Meter is electrically operated, which allows proper flexibility for securing these necessary records and permits centralizing these valuable records at the point where they can be conveniently read and are therefore still more valuable. Request complete details at once.

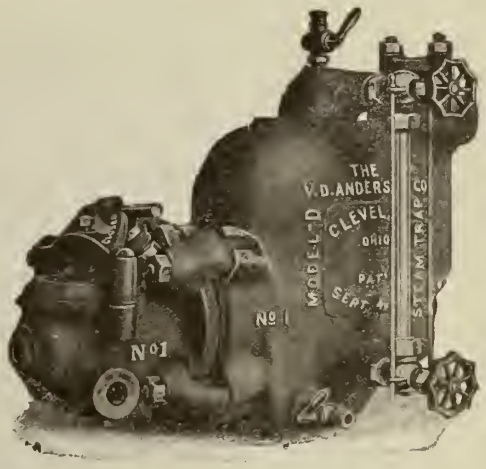
Stays Tight

The ANDERSON Steam Trap will Save You Expense, Time and Trouble

Install it in Your Boiler Room



Maintained steam tightness is what counts. When you install an Anderson Steam Trap you can depend upon it staying tight even under the most severe conditions.

Not only on the first day that you place it in service—but every day thereafter it will continue to be tight with the least attention on your part.

Will not leak steam with just ordinary care.

Fitted with a large interchangeable valve and seat, maintained under a 3-inch water seal.

You can tell at a glance whether the trap is working properly or not by means of an outside gauge glass. The practical operating man appreciates the self-contained by-pass and removable strainer and gauge glass—"Anderson" features that show the efficiency of the draining.

Why not investigate it further:

BETSON'S TRADE MARK PLASTIC FIRE BRICK

On Your Next Furnace Lining Job

B ECAUSE YOU have had your troubles year after year with the ordinary fire brick or blocks—is one very good reason why you should use something better on your next furnace lining job.

E VERY ONE knows that it's the joints in the brickwork that make the ordinary furnace linings come down. The varying temperature in the furnace causes the mortar to crumble and so the bricks or blocks fall out.

T HESE TROUBLES can be overcome by making the entire lining in one piece so there will be no joints. And the one-piece monolithic furnace lining is practicable. Betson's Plastic Fire Brick has made it so. Betson linings are durable, gas-tight linings.

S O, in those plants where continuous operation is paramount and where the boilers are always on the load, the chief depends on Betson's Plastic Fire Brick. Service counts most, and Betson's has a service record of 20 years. It comes in the yellow-top barrel, ready for use.

O NE MAN CAN DO the job—any handy man around the plant. There is no need paying for special blocks and experts to lay them. So, in your next furnace lining job, use Betson's Plastic Fire Brick. It's good for every other part of the boiler, too.

N O SPECIAL TOOLS are required and no forms are necessary for laying up Plastic Fire Brick. You just place it in chunks, pack it with a mallet, then smooth with a trowel—and the job is done.

S END YOUR ORDER to-day. Five to ten barrels of Betson's Plastic Fire Brick will do your next furnace lining job complete. For repairs, two or three barrels will serve. After that, you will be a Betson booster.

Ask for Practical Booklet—It Will Interest You

There Is Only One Plastic Fire Brick

Inside Facts About Heating the "Dunham Way"

The Dunham Radiator Trap is distinctive in the simplicity of its construction.

It is this fact that makes a Dunham Heating System so simple, yet so efficient.

The Dunham Radiator Trap is the heart of Dunham Heating. It gets rid of all air and water from the radiator, but holds the steam in until every last bit of heat is given off. It does this automatically—no noise—no air valves on the radiators.

Dunham Heating is standard where efficient and economical operation is desired.

Dunham Heating Service, in advising on heating problems, is given without obligation.

Complete details on request.

"Yes, We Skinned This Tool Steel Mandril in Breaking the Jeffrey Chain Roller"

"The labor scarcity hit us hard several months ago, so we were compelled to substitute mechanical equipment wherever possible. We could not afford to pay war-time wages for handling coal and ashes after we learned the economy of Pivoted Bucket Carriers on this work. But before we selected our Carriers we made a number of thorough tests—and the Jeffrey Carrier showed up fine on every one.

"The Jeffrey People told us that the Chain Rollers were so hard and tough that the bores have to be turned out on a grinder instead of in the usual way on an engine lathe.

"However, we split one of the Rollers with a tool steel mandril and were convinced. The case-hardened mandril was actually skinned by the tough metal of the Roller."

Catalog No. 210-4 will tell you about other tests that proved rugged, dependable construction, and shows in addition many interesting illustrations of the Jeffrey Carrier."

Mnufacturers of Hack Saws Unexcelled

Have The Maritimes Had Fair Play?

THE Maritime Provinces did not enter Confederation very willingly and it may surprise people in other parts of the Dominion to learn that at the present time the people of New Brunswick and Nova Scotia are not altogether pleased with the results of the bargain. There is a distinct feeling among them that the advantages of Confederation have gone to the other Provinces. In the course of an article in the July issue of MACLEAN'S MAGAZINE, Thomas M. Fraser explains why this feeling has grown and the basis for it.

This article was written for the purpose of letting the other provinces know that the feeling exists but it will be of intense interest to people in the Maritimes. Be sure to read it—"The Spirit of the Maritimes."

"The Land of National Leaders"

An article on the political aspect of the Eastern Provinces and the achievements of their leading statesmen.

"Guarding Our Coast Line"

An extremely interesting description of the measures that were taken to patrol and guard the Atlantic seaboard during the war.

Bonar Law, the man from the Maritimes, who has been the able lieutenant of Lloyd George at all crises in Great Britain, appears on the cover in a handsome three-color reproduction.

Other Big Features of the Number

"With the Snowball Brigade"

By Captain Louis Keene

Just back from Siberia—Captain Keene tells some sensational and intensely gripping things about conditions in that country which the Canadian forces are helping to stabilize. It is a record of international complications, strange atrocities and almost unbelievable living conditions.

"The Three Tommies"

By Robert W. Service

A war poem of unusual strength.

"Solving the Problem of the Arctic"

By Vilhjalmur Stefansson

The fourth instalment of his remarkable story of the five years he spent in the north for the Canadian Government, appearing exclusively in MACLEAN'S.

Three Magnificent Stories

The best fiction obtainable is found in this issue: "Owners Up," a race horse story by W. A. Fraser; "His Majesty's Well Beloved," by Baroness Orczy; "Bunkered," by Allen C. Shore.

The Review of Reviews

Here are a few of the articles in this splendid department chosen as the best published during the past month in all magazines:

Finding Husbands For Three Million Women.
Will England Become an Agricultural Country?
Germany Can be Prosperous Under the Peace Terms.
The Woman Who Wrecked the World.
The Great Lama Rides in Motor Car.
Strange Personalities at Paris.
Making All Men Equal.
Winning the Secrets of the Desert.

JULY ISSUE *Now On Sale At All News Dealers* ***20c.***

If there are no newsdealers in your town, or if your newsdealers cannot supply you, send 20 cents for a sample copy or $2.00 for a whole year's subscription to MACLEAN'S MAGAZINE, 143-153 University Avenue, Toronto, Canada.

"There's no Trouble *Now*"

"I've found the right packing at last—one packing that serves everywhere in the plant. I am all through with leaky flange joints and I don't have half a dozen different kinds of packing cluttering up my supply room. I use the same packing for every purpose—

VULCABESTON

Red Fibre Sheet Packing

"It is made of long fibre asbestos, which will not squeeze out or creep, yet has greater resiliency than any other packing I've ever used.

"Vulcabeston Red Fibre Sheet Packing goes in *every* flange joint in *every* pipe line from now on—high and low pressures, superheated steam, acid and ammonia—and on all engine and pump cylinders, too."

If your regular dealer does not carry Vulcabeston—"the universal packing"—write us direct.

The Johns-Pratt Company
Hartford, Conn., U.S.A.

1/4

of the coal mined is wasted in burning

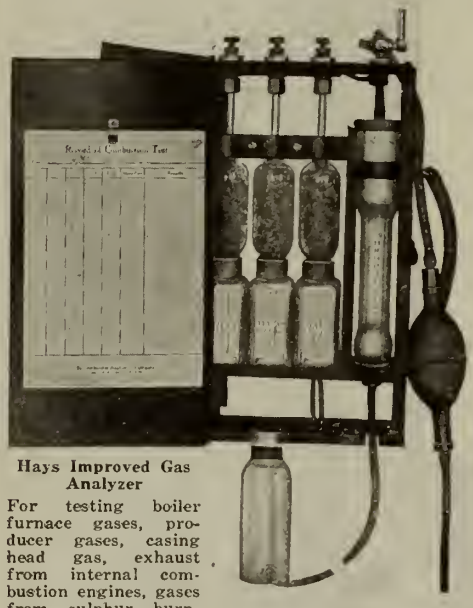
Save ONE Carload in Every FOUR

Reduce Your Steam-Cost 25 Per Cent.

Improper draft, holes in fire, leaky settings, improperly timed firing periods and other common *causes of fuel waste* can be easily detected when you have the records of

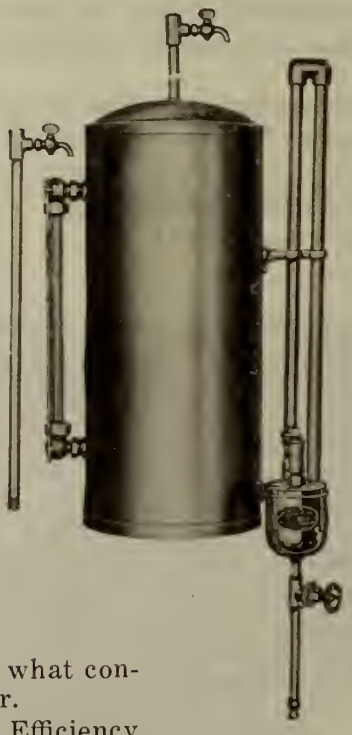
"HAYS" Combustion Apparatus

before you. And knowing is the first necessity of taking corrective measures.



Hays Improved Gas Analyzer

For testing boiler furnace gases, producer gases, casing head gas, exhaust from internal combustion engines, gases from sulphur burners, nitric acid gases, chlorine gas, etc., etc.



Gas Collector with water-flow regulator.

Hays Automatic CO_2 and Draft Recorders, Automatic Gas Collectors, Draft Gages and other Hays Equipments installed on your boilers keep you posted as to just what conditions your boilers are operating under.

In hundreds of plants, Hays Combustion Efficiency Appliances are leading the way to increased efficiency in boiler firing, a most effective way in **offsetting high coal prices.**

May we send you our Book "HOW TO BUILD UP FURNACE EFFICIENCY." It tells how fuel is wasted, how to stop that waste and keep it stopped.

The Hays Differential Draft Gage indicates the draft over the fire or the drop in draft through the boiler.

Howard Guided Expansion Joints

Howard Guided Expansion Joints put the "How" in all expansion problems. The high pressure and superheat of modern engineering practice have added tremendously to pipe line dangers and the engineer's troubles.

"How" to take up the greatly increased expansions and contractions while at the same time keeping joints tight under the greater pressures?

That is the question to which HOWARD Guided Expansion Joints are the exclusive and satisfactory answer.

MAXIMUM OF TRAVERSE is the first essential of an expansion joint. Here the HOWARD excels with its full 4 inches of play between the "cold" position (see cut above), and the "hot" position. Assuming the outside temperature is 32 degrees, this 4 inch play amply takes care of the linear expansion in more than 100 feet of wrought iron pipe at any pressure from 30 to 300 pounds. Very often one HOWARD, by its greater capacity, takes the place of two or more other expansion joints.

Inquire about this to-day.

Scale in Your Boilers

Clean Tubes Mean Coal Saving

And easier firing, less ash-handling, fewer shut-downs, prevention of bagged or burned tubes, fewer repairs, and less frequent wash-outs. METLSKIN can pay for itself in a short time.

is an unprofitable boarder. Its appetite is enormous and it consumes far more than it is worth. Why not give it TWO MONTHS' NOTICE, and put an end to your loss thereafter?

THE SIXTY-DAY TEST OF METLSKIN is open to any reliable concern that is troubled with boiler-scale, pitting or corrosion. A small daily dose of METLSKIN, for a period of two months, will bring down the most tenacious scale, and absolutely convince you that A CLEAN BOILER IS NOT ONLY POSSIBLE, but EASY.

SEND A POSTCARD for the METLSKIN booklet and learn about Our Offer, Guarantee Bond, and Prices.

METLSKIN is neither "Compound" nor "Cure-all."

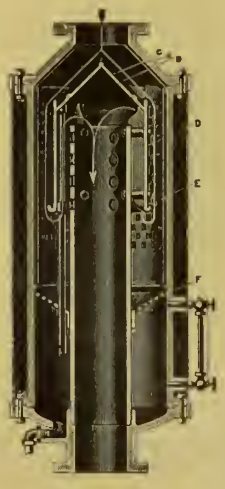
III IMPORTANT THINGS

TO CONSIDER ABOUT
A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

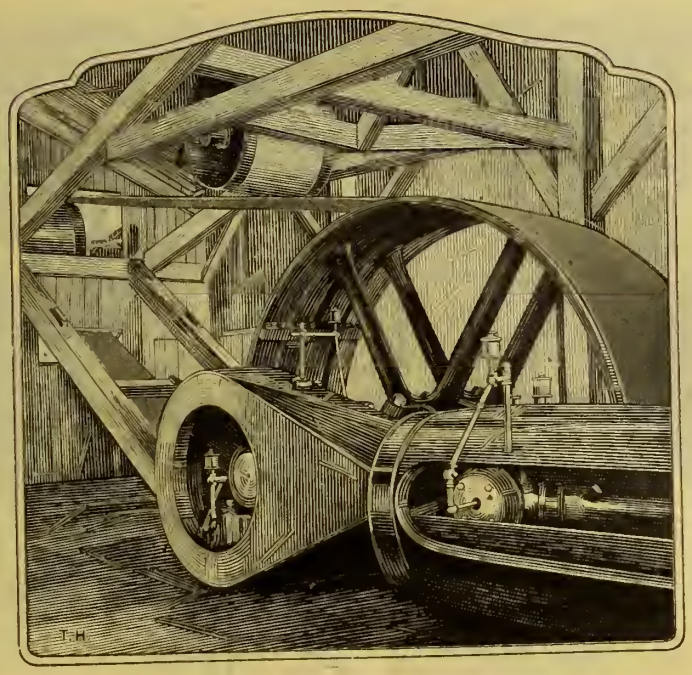
FAIRBANKS-MORSE
EVERYTHING MECHANICAL

Through the scientific investigation of our Engineering Department, all the factors which enter into the design of a belt have been standardized. According to best modern practice, belts are designed with an overload capacity of about 60%. Such ratings are found to give the lowest cost per horse-power transmitted per year.



48" Heart 3-ply Belt, 86 feet long, installed in 1911 in the mill of the C. A. Smith Lumber Company, Baypoint, Cal. Driving Pulley, 14 feet, 101 R.P.M. Driven Pulley, 4 feet. Belt Speed, 4400 F. P. M. Theoretical horse-power, 600. Actual horse-power transmitted, 850 to 900. Cost of Belt, 1-5 of 1c per horse-power per week.

"Where Little Things Are Big"

Think what this belt must do. Travelling at 4,400 feet per minute, it makes its circuit fifty times every sixty seconds. For every one of these revolutions, each part of the belt must slacken and tighten itself, practically once a second.

To be efficient, it must do this without loosening its grip on the pulleys, without jumping or slipping,. That this 48" Heart Belt does transmit power efficiently is evidenced by the fact that it is delivering 250 more horse-power, or over 40% in excess of that for which it had been designed. It has been doing this for over 8 years.

The test of such conditions seems impossibly severe, and yet this belt succeeds because it is made from the right material—leather—which has retained so many of the wonderful properties that fit it to be the skin of a powerful, active, living animal.

In order that our leathers may meet these almost impossibly severe requirements of elasticity and pulley grip, we tan them ourselves specifically for belting use, handling 1,000 hides a day.

That we may offer always the right belt for the required work, we make our Standardized Series of Leather Belting—a Belt for each class of power transmission. Standardized in manufacture, and standardized in application to the work to be done.

Many of the best belted plants ask us to specify the belting for every *pulley* drive. Try the plan yourself. Then, when buying, call for "Graton & Knight—Brand or equal." This won't commit you to buying our belts. It will put your buying on the one basic consideration—the work to be done.

The Heater Without the Usual Heater Troubles

No corrosion
No split tubes
No leaky heads
No expansion strains

Alberger Multi-Head Water Heaters

AND IT WORKS FAST, TOO, HEATING WATER AS FAST AS IT IS DRAWN. IN FACT IT TRANSMITS 50% MORE HEAT THAN ANY STRAIGHT TUBE HEATER.

The small, corrugated, pure copper tubes in this Alberger Heater expand into a floating head independent of the cast iron shell, which means that there cannot be trouble from expansion or contraction strain.

These corrugated tubes will remain scale-free longer than a heater with plain tubes, because the corrugations promote a scouring effect on the tubes.

May we send catalogue describing both Horizontal and Vertical Types? No obligation whatever.

A further Demonstration of the Excellence of
MAGNOLIA METAL

PERKINS MACHINE & FOUNDRY CO. INC.,
Founders and Machinists.
Amsterdam, N.Y.

Magnolia Metal Co.,
New York City.

May 13, 1919.

Gentlemen,—The writer has been using MAGNOLIA METAL for 18 years with excellent results.

Have used MAGNOLIA on Dynamo and Engine Bearings (Connecting Rods more particularly) and claim it to be the most excellent metal for hardest service obtainable. Am glad, indeed, to be able to rcommend it.

Beg to advise you that I am a mechanical man of many years' experience, having handled all kinds of Babbitts, and MAGNOLIA METAL is my preference.

Yours truly,
PERKINS MACHINE & FOUNDRY CO.,

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways.

W. C. McGHIE, Chairman of Board.

W. A. RIDDELL, M. A. PH. D., Superintendent, Trades & Labour Branch.

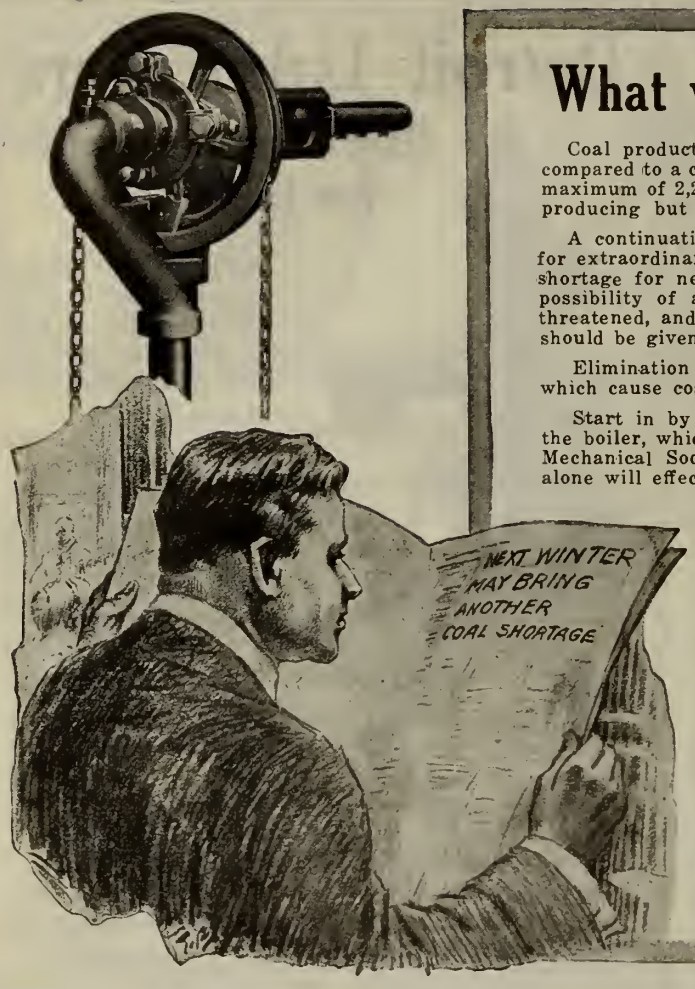
174 N. Market St., Chicago, Ill.



What will you do next winter?

Coal production is at the lowest possible point in three years. As compared to a combined 1917 production of 1,800,000 tons daily, and a 1918 maximum of 2,200,000 tons daily, Canada and the United States are to-day producing but 1,167,000 tons.

A continuation of this condition beyond the present month will call for extraordinary production during the remainder of the year if a fuel shortage for next winter is to be avoided. Combine this fact with the possibility of a coal miners' strike in the early fall, which has been threatened, and there is very good reason why the boiler room problem should be given serious consideration NOW!

Elimination of methods and practices of the boiler room operation which cause coal waste is an intelligent step in the right direction.

Start in by discarding the hand hose and lance system of cleaning the boiler, which is only 50% effective, and replace it with the Diamond Mechanical Soot Blower System, which is 95% effective. This change alone will effect the following economies:

1. FUEL: a saving of 4 to 8 per cent.
2. BOILER EFFICIENCY: an increase of 4 per cent.
3. LABOR: a saving of many hours per day.
4. LONGEVITY: an increase in the length of service of the boiler tubes through the prevention of corrosion.
5. STEAM: a saving of 25 to 75 per cent. of steam used for cleaning.

Diamond Soot Blowers are in use in hundreds of plants in Canada.

For lists of these users and full information write for Bulletin 170.

Babbitt
—Adjustable—
SPROCKET RIM
with Chain Guide

JUST A PULL OF THE CHAIN

THAT is all that is necessary to operate the most inaccessible valve when the Babbitt Adjustable Sprocket Rim is used. Easy to attach, and at little expense, it eliminates the use of dangerous step ladders, and delays in operating valves, when such delays may be vitally important.

Write for a catalog.

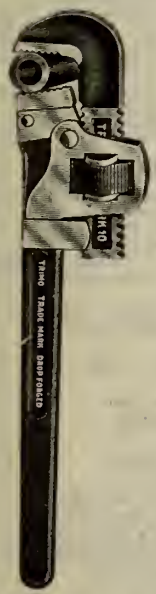
The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH



Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

Inquiries from Importers and Dealers Solicited. Send for Catalogue No. 55.

TRIMONT MANUFACTURING CO.

Cable Address: Triwrench

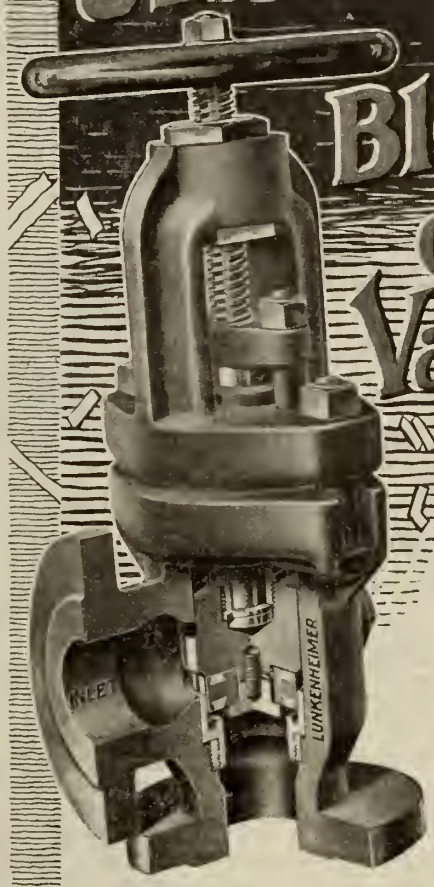
Roxbury (Boston) Mass., U.S.A.

The ULTIMATE in Blow-off Valves



The "Duro" has demonstrated its peculiar adaptability as a blow-off by many years of satisfactory service, with a minimum cost for upkeep.

The self-cleansing seat feature prevents an accumulation of sediment on the seating faces during the blow-off, thereby reducing wear to a minimum and preventing leakage while the boiler is in operation.

To further enhance the durability of the valve, the disc is reversible; the disc face can easily be replaced with new material in case of wear, and all the parts, including the seat ring and reversible disc are renewable.

The materials and workmanship are of characteristic Lunkenheimer "Quality."

Specify **Lunkenheimer "Duro"** and insist on their installation.

Write for descriptive booklet No. 515DC.

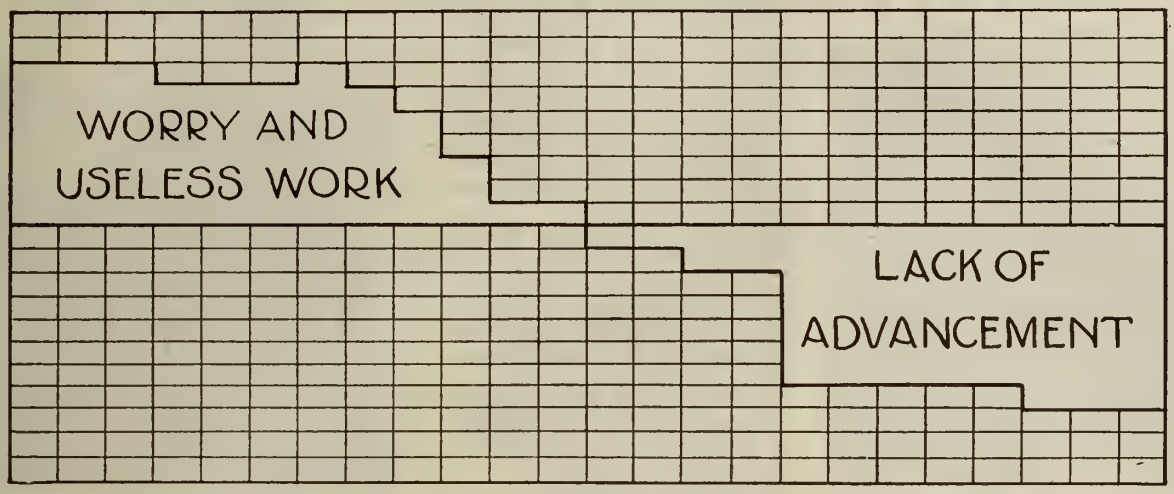
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

J. H. HALE, General Secretary,

Does Your Storage System Save Oil?

If you have never studied the question of storing, distributing and using oils, you will be surprised to know the enormous losses that occur daily wherever oils are handled by inefficient methods. Losses that could easily be prevented by use of

BOWSER OIL STORAGE SYSTEMS

Such Conditions Are Wasteful, Dangerous, Unnecessary

Save All the Oil!

Store oils in leakproof, dirt-proof tanks. There is no loss of oils from any source, no loss of quality. Labor in handling is cut to the absolute minimum.

Write for literature describing equipment for your needs.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compress

Marsh and American Pumps are especially adapted for long, hard service because are *extra heavy* in design and of *extremely rigid construction*. Every unit is built a strong to withstand 24-hour-a-day service and to stand up under any unforeseen st which may be placed upon it. Piston rods on the steam pumps are extra large made of solid bronze. The water ends are equipped with heavy cast bronze remov bushings.

This superior construction not only insures continuous and satisfactory operation, practically *eliminates expensive shut-downs*. Marsh and American Pumps are the duct of over 25 years' experience in the design and construction of high grade pum machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both si and double suction types which are designed for heads up to 125 feet. They equipped with wide ring oiled bearings and the single suction type has overhan casing enabling the discharge to be taken at any angle desired.

Economiser Practice in Great Britain

From

"Engineering"

Nov. 1, 1918

EXACT DATA ON THE RUNNING OF STEAM BOILER PLANTS No. 1

By D. BROWNLIE, B.Sc.Hons.(Lond.), F.C.S.
J. COMPSTON, and H. W. ROYSE.

(Extracts from above article)

The economizer is, of course, an absolutely essential part of any up-to-date boiler plant, and the saving obtained should be 17½ per cent. to 20 per cent. under average conditions. In this connection to be saving 15 per cent. or over, given in Table II, the figures of each of the separate 24 plants found will be of interest, showing what is actually being done on many boiler plants.

The other advantages of the economizer are the reduction of the strain on the boilers by the provision of a high-temperature feed water preventing unequal expansion and contraction, and also that there is always a large reserve of hot water at hand for any sudden demand for steam. Further, the evaporative capacity of the boilers is greatly increased.

TABLE II.—DETAILED RESULTS OF WORKING OF ECONOMIZERS IN 24 PLANTS SAVING OVER 15 PER CENT.

No. of Plant	Average Temperature of Feed Water		Average Temperature of Flue Gases.		Draught in Inches		Steam Pressure Gauge.	Total Evaporation on Plant per Hour.	Number of Tubes in Economiser on Plant.	Per Cent. Saving due to Economisers.
	Before Economisers.	After Economisers.	Before Economisers.	After Economisers.	W.G. Chimney Base	Side Flues or Downtake Boilers.				
	deg. F.	deg. F.	deg. F.	deg. F.			lb. per sq. in.	lb.		per cent.

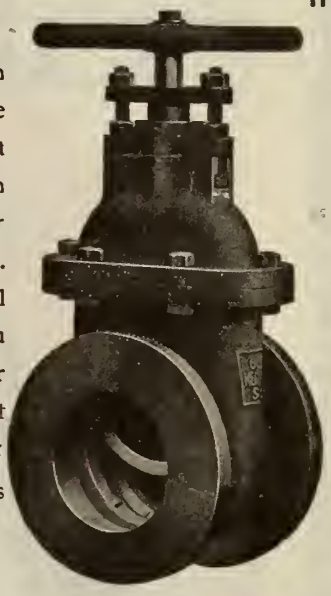
KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.



When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

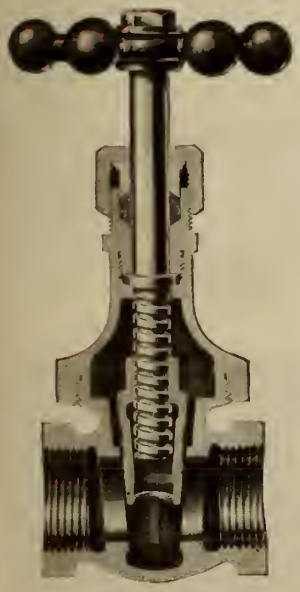
TRADE PENBERTHY MARK TRADE PENBERTHY MARK

COMPODISK

WE HAVE TALKED WITH a great many progressive and on-to-their-job Engineers throughout the country, and they tell us frankly that the "Outside Bonnet Construction" (found in all Penberthy Valves) is the most sensible and practical improvement ever made in brass valves, for this reason:

ALL Penberthy Valves are designed with outside threads on the bonnet end of the valves. When tightening down bonnet to place, this construction prevents spreading or enlarging bonnet end of body, causing a loose fitting and unsafe valve. The threads, being on the outside of the body, are immune from the corrosive action of the steam and water, preventing the body and bonnet from freezing together, eliminating all strains, and making an extraordinary strong valve at the vital point where others are weak.



BRASS GATE "With the outside bonnet" Registered and Approved.

Look for our name on the Valve you buy. It's your guarantee of valve comfort and economy.

COMPODISK Discs are interchangeable with other standard makes on the market. They will stand high steam pressure and severe conditions without cracking or flaking and have a record for long and efficient service.

When Production Costs Are Mounting

COMPETITION knows no favorites. The very life of your industry depends on keeping down production costs. When these soar high, one good place to look for a solution is in your power plant. Study the conditions under which your machinery works.

Rigid mechanical efficiency is only maintained by careful, systematic, **correct** lubrication. Select your lubricants with the same scrupulous care with which you choose your machinery; be sure they are the **proper** lubricants as well as the best; remember that poor lubricants are expensive at any price.

Imperial Lubricants are a full line, scientifically formulated for all types and parts of machines. Among them is a correct lubricant for each requirement. They are made in Canada, of uniform high quality, thoroughly dependable, always available and recommended by experts everywhere.

Imperial Lubricants

- Imperial Bayonne Engine Oil
- Imperial Kearsarge Engine Oil
- Imperial Renown Engine and Dynamo Oil
- Imperial Solar Red Engine Oil
- Imperial Standard Gas Engine Oil
- Imperial Junior Red Engine Oil
- Imperial Eldorado Engine Oil

Imperial Lubrication Engineers are glad to give you, without charge, the benefit of their knowledge and experience. They will be pleased to co-operate with your own mechanical engineer in making investigations and recommendations for the correct lubrication of your plant.

You should do everything possible to keep your mechanical operation costs down to the lowest figure. Do not hesitate to call Imperial Lubrication Engineers for consultation. Write us at our home office, 56 Church Street, Toronto.

Many of Canada's Largest and Most Efficient Power Plants

SHOW A PREFERENCE FOR

D. K. McLaren's Genuine British Oak Tanned Leather Belting

THERE'S A REASON: **The test of time has proved that the length of service is the only true way to judge the quality and value of belting.**

Many of Canada's largest power plants have put D. K. McLaren's Belting to the quality test and have found it satisfactory in every way as is proven by the fact that the biggest percentage of our business comes in the form of repeat orders.

The great success of D. K. McLaren's Belting is due to the fact that only the flawless backs of the hides of choicest steers are used and these are tanned by the genuine British Oak process, the best known for preparing belts for hard service. Every bit of the hide's natural strength is preserved. Minimum stretch, minimum slippage and fewer breaks are the results you can expect.

May we put you in touch with users so that you can profit by their experience.

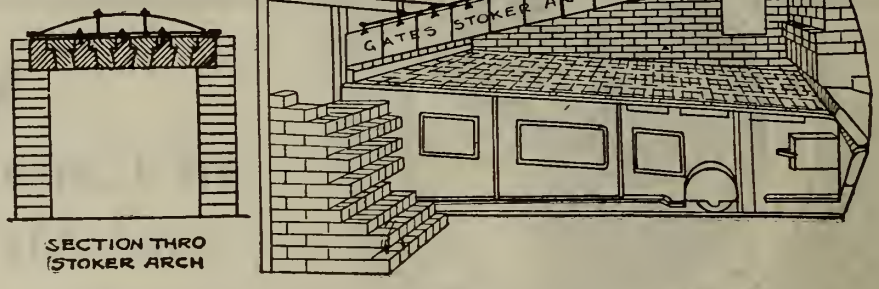
GATES STOKER ARCH



BUILT on the unit principle, any section of the arch can be placed without disturbing the rest of the brick work. Saves both time and money in making repairs—and frequently saves expensive shutdowns.

The Gates Stoker Arch minimizes stoker arch maintenance cost.

Our new type of arch block is adapted to Dutch oven type of boiler setting, or H.R.T. boiler back arches, large fire door arches, reverberatory and smelting furnaces as well as stoker arches.

If your setting is not standard we will design a block to suit your requirements.

We specialize in all kinds of POWER PLANT BRICK WORK.

Call on our engineers at any time for information you may require. Their services are offered to you without obligation.

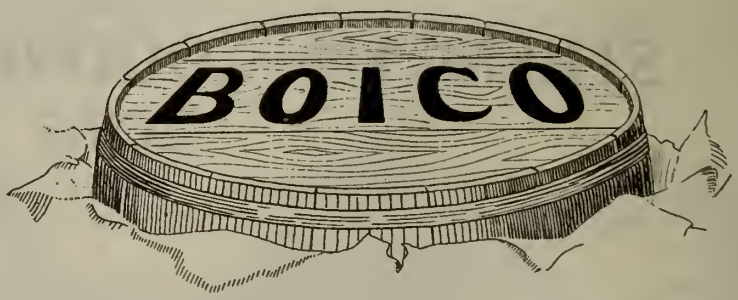
The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**
BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.



Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Most Efficient Boiler Feeder

LUNKENHEIMER AUTOMATIC INJECTOR

Will deliver more water per pound of steam and the capacity is diminished in a lesser degree by long lifts and hot feed water than any other Injector made.

This is due to the scientific design of the tubes, which are proportioned for maximum delivery, and it maintains its maximum delivery in service, because the tubes are made of a special **hard bronze** which is peculiarly resistive to the inevitable and severe erosive action of the saturated flow at high velocity. Besides, the Lukenheimer design of "spill" eliminates the rapid wear of the combining tube.

The wide range of operation of the Lukenheimer Injector; its instantaneous restarting after a temporary interruption of either the steam or water supply; its durability and the interchangeability of parts, are details which merit the consideration of every user.

Write for descriptive Booklet No. 504DC—which contains valuable information on the care and operation of injectors.

48" Heart 3-ply Belt, 86 feet long, installed in 1911 in the mill of the C. A. Smith Lumber Company, Baypoint, Cal. Driving Pulley, 14 feet. 101 R.P.M. Driven Pulley, 4 feet. Belt Speed, 4400 F.P.M. Theoretical horsepower, 600. Actual horsepower transmitted, 850 to 900. Cost of Belt, 1-5 of 1c per horsepower per week.

"WHERE LITTLE THINGS ARE BIG"

Think what this belt must do. Traveling at 4400 feet per minute, it makes its circuit fifty times every sixty seconds. For every one of these revolutions, each part of the belt must slacken and tighten itself, practically once a second. To be efficient, it must do this without loosening its grip on the pulleys, without jumping or slipping.
This 48" Heart Brand Belt is one of the Standardized Series—made according to the work to be done. It has been running over 8 years.

Write for "Standardized Leather Belting" Book.

Cross Section Showing Furnace Construction

Burn Any Fuel

Coals that nobody wants are welcomed by the MURPHY FURNACE.

During past coal famines many a plant kept its equipment operating by burning such fuels as slack, lignite, sawdust or even refuse in

MURPHY AUTOMATIC FURNACES

While, of course, bituminous coal produces the most economical results, the MURPHY FURNACE, however, will burn such fuels efficiently enough to keep a plant operating during emergency.

The Murphy construction is such that it feeds the fire from two sides (not one) giving double the coking area. The coal is fed —the fires cleaned — the ash removed — continuously and automatically.

Couple Murphy ability to burn any kind of fuel with natural draft and you have a simple explanation of Murphy economy in hundreds—yes, thou ands—of plants.

You will be surprised to know how easy the MURPHY FURNACE can be installed under any type of boiler—50-H.P. and up.

Large Murphy Ca.alog HM-7 sent on request.

For information on RILEY UNDERFEED STOKERS for large boilers, see July 5 advertisement or send for Riley Stoker Catalog HR-7.

Jenkins Bros

Jenkins Bros.' Equipment Stands Up Under Severe Strain

During the great flood in Ohio in 1912, the engine room of the Dayton City Railway Company was completely submerged. In this room Genuine Jenkins Bros.' Valves, Pump Valves and '96 sheet packing were under nine feet of water. This Jenkins Bros.' equipment was subjected to the severest of strains, yet it came through this extraordinary trial without injury. Thus the **quality** of **Jenkins Bros.'** Products was clearly exhibited. The reputation for dependability of Jenkins Bros.' Valves lies in their ability to withstand excessive service wherever and whenever called on to do so.

For over 50 years, thousands of plants and buildings have been using Jenkins Bros.' valves, because they know they are dependable. They know that the Jenkins Bros.' guarantees are conservative, and that whenever necessary, Jenkins Bros.' valves stand up even under occasional excessive strain.

STEADY steam pressure is a vital factor in making good paper. A sudden drop at the gauge might mean serious loss in the mill. Keeping up steam is a matter of prime importance.

That is why modern paper mills are equipping their power plants with COPPUS Turbo Blowers to maintain constant steam pressure under varying conditions of load, fuel, and weather.

For instance, the COPPUS Blowers shown above operating in the plant of the Hampshire Paper Company, makers of good paper, at South Hadley Falls, Mass., have kept steady steam pressure with very satisfactory results. Peak loads are quickly met, steam pressure is always constant, and cheap fuel is economically burned.

COPPUS Turbo Blowers are helping out engineers and speeding up boilers in power plants the country over. Their good work is not confined to the paper industry—it extends wherever power is used and coal is burned. If they are not already working for you it is likely that they could save time, money and labor in your boiler room.

Catalog H11 tells how "COPPUS Equipment can save you money."

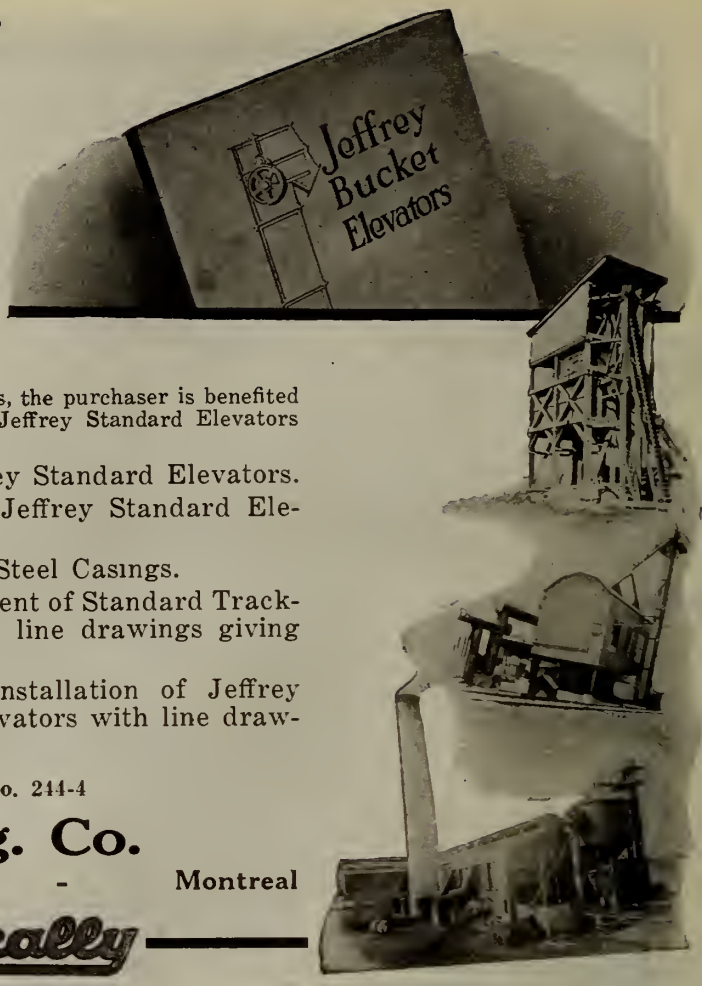
COPPUS TURBO BLOWER

A Valuable Book for Engineers, Contractors and Manufacturers



The outstanding feature of the new Jeffrey Catalog is the ease with which a Jeffrey Standard Elevator can be selected from the 40 pages of complete layouts and specifications to exactly meet your requirements.

In addition to saving the expense of layouts and drawings, the purchaser is benefited by a quicker delivery made possible by the placing of Jeffrey Standard Elevators upon a manufacturing basis.

Some of the examples and subjects outlined in this book.

- Capacity of Jeffrey Standard Elevators.
- How to select a Jeffrey Standard Elevator.
- Jeffrey Standard Steel Casings.
- General arrangement of Standard Track-hoppers with line drawings giving dimensions.
- Suggestions for installation of Jeffrey Standard Elevators with line drawings.

Handle it Mechanically

Dominion Belting Company, Limited
Hamilton, Canada

Sole manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.

"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO. Ltd., Hamilton, Canada-Quebec Branch: 51 Duluth Bldg., Montreal

ECONOMIC Carling BLOWERS SUPERIOR

Carling Turbo Blowers

For burning the lowest grades of coal successfully, getting all the heat value from the fuel. For positive draft with Automatic Control and steady steam pressure. For obtaining the ultimate capacity from the boiler.

Carling Blowers are low in first cost, easy to install and make a quick return on the investment. We will be pleased to show you why it pays to use Carling products.

Niagara Falls from an Historical Standpoint

It is Often of Interest to Look Back Over the History of Natural Wonders Useful to Man, and Niagara Falls is a Case in Point for Its Origin Dates Back to Comparatively Recent Times

By J. F. HEFFRON

TO engineers, many of whom have written of the great cataract, Niagara is generally regarded as a gigantic piece of machinery, the greater part of whose energy is accomplishing nothing but the pounding out of its own life on the rocks which form its bed.

Since the Horseshoe Falls, half a mile long and 155 feet high, together with the American Fall, 1,400 feet long and 162 feet high, discharge 222,000 cubic feet of water per second at mean water level, equal to about four million horsepower, of which less than 500,000 horsepower has been actually developed, engineers have not exaggerated the wastage which occurs. There are others though, among men who have been moved to view the great cataract from another angle, and it is with this view we propose first to deal.

BIRD'S-EYE VIEW OF NIAGARA FALLS AND VICINITY.

Perhaps the most interesting part of the study of Niagara's geological and physical history is the record of the attempts that have been made to determine its age. To the scientist, geologic time presents one of the most difficult problems with which he has to deal. When the various periods into which he divides the history of our globe are numbered by hundreds of thousands, and millions of years, the human mind is appalled at the prospect, and when the calculations of different geologists regarding the age of the cataract vary by thousands of years, the lay mind cannot help becoming somewhat credulous, and at times be tempted to discard the whole mass of scientific data relating to the subject.

Man, however, actuated no doubt by his inveterate egotism, is prone to measure all things in relation to, and by comparison with himself and with his short span of existence. Because of this fault he looks naturally upon the great wonders of the world as destined to last as long as the earth itself. He fails to realize, for instance, that our hills and mountains are slowly crumbling before our eyes, or that our rivers are slowly but surely carrying the matter forming these prominences on the earth's surface toward the sea, filling the lakes and lower portions of the land along their courses. These slow, almost imperceptible, but ceaseless forces are ever at work reducing the earth's surface to that of a level plain, and at the same time depriving the land of its lakes by filling their depressions with silt. The winds and the waters, together with the wearing power effected by frost, constitute the forces struggling with this gigantic task.

Let us observe also, that the calculation of the life of Niagara is interesting in itself even if we overlook any other great questions that can be settled by the solution of the problem of its age, such as the probable number of years that the river shall exist in its present form, the many centuries that have elapsed since the ice retreated from this region, and certain facts concerning the antiquity of man on this part of the earth's surface. In order to make a proper study of the problem regarding Niagara's probable age, we must review carefully the conditions that existed at the time a great ice sheet covered this district, and also the changes which were undoubtedly effected in the contour of the earth's surface in this district during the northern retreat of the great glacier that one time covered it.

The Niagara River

It was undoubtedly during that period in the history of our planet known as the last glacial epoch that the greater part of the present Niagara River was formed, but the conditions of the glacier epoch were so abnormal that they have long made it difficult for the geologist to substantiate a vast number of inferences drawn from present conditions concerning this prehistoric time.

The Niagara River, nevertheless, forms perhaps the best means in the world for determining the lapse of time since the last "ice age." The best material in existence is found here for this study and has led to exhaustive scientific analysis of every clue presented by the cataract and the massive gorge it has cut through the limestone and Niagara shale forming it bed.

If we observe a relief map of the Niagara district it shows at once that the formative forces which gave to it its present characteristics were at the highest stage of their development when the lands to the south had almost reached their present stage, and that the Niagara district is therefore a comparatively new region. The wonderful work of the great cataract itself is going on before our very eyes, and the history of this great river is now working itself out at the height of its glory, in our age, when all can behold. It is especially interesting since it is the only example of the kind known.

Time was, before the excavation of the present gorge had begun, when the water flowed along the top of the plateau extending from Lake Erie to Lewiston, where the Falls were then situated at the latter point.

In remote times the waters of Lake Erie did not find an outlet through Niagara River, so there was no channel ready made for the river when it began its present course. Even after the birth of the river the upper lakes, Superior, Michigan, and Huron, did not discharge their waters through Niagara, and as it is only in comparatively recent times that the waters from Lake Erie discharge through this channel, but a small fraction of the present volume could have been at work on the Fall for some time. The most prominent features of the present river are therefore modern, and hence have been very little affected

by those agencies which are continually remoulding the contours of all land surfaces. The inclination of the river's bed has undoubtedly varied greatly with the ages. This has been due to a gradual uplifting or depressing of the earth's crust, and there seems to be abundant evidence that great changes of land level occurred in the northern hemisphere, first in its depression during the glacial period and again in its re-elevation after its close. Dr. G. Frederick Wright, F.G.S.A., assures us that this post-glacial depression amounted to six hundred feet at Montreal and over a thousand feet in the more northern latitudes of North America, this condition applying also in corresponding latitudes in Northern Europe. There is, also, he tells us, distinct evidence of a depression in Central Asia amounting to seven hundred feet, and considerable evidence of its extension to two thousand feet. The floods connected with the final melting of the ice were enormous in amount and incalculable in their destructive effects on the animal life of that time.

During that period of glacial floods it is estimated that the Missouri River was compelled to handle, during the summer months, twenty-five times its present volume of water, resulting in floods over two hundred feet in height, while the Mississippi River was compelled, at the same time, to dispose of some sixty times its present volume; consequently the current of the Niagara River has varied greatly in velocity with these changes of elevation and depression of the land surface. A calculation therefore, of the work done by the river during each epoch of its history is surrounded by many difficulties. Continued investigation has been made along this line which now seems to have resulted in a rather satisfactory measure of success.

The Niagara River, as we will observe by looking at a map of the region, has its origin in the eastern end of Lake Erie, at a point which is about three hundred feet higher than the surface of Lake Ontario. From Erie to Ontario the descent is not gradual, although after leaving Lake Erie the river's waters meet no obstructions until the head of Goat Island is reached. The river has no valley and the country is so nearly level that its waters present more the appearance of an arm of the lake extending over this region than they do a flowing river. The earth's surface in this district presents a gently rolling plain with almost no slope for nineteen miles until the shore of Lake Ontario is nearly reached. At this point, just above the towns of Lewiston and Queenston, we find ourselves looking over a high precipice affording a magnificent view of the lower lake (Ontario). This cliff is known to geologists as the Niagara escarpment. By the descent of the rapids above the Falls and the Falls itself, the waters take a drop of two hundred feet, and thence rush through the deep gorge at a rapid rate, continually descending lower through the whirlpool and on to Queenston, seven miles distant, at which point the current becomes more moderate as the level of Lake Ontario is reached.

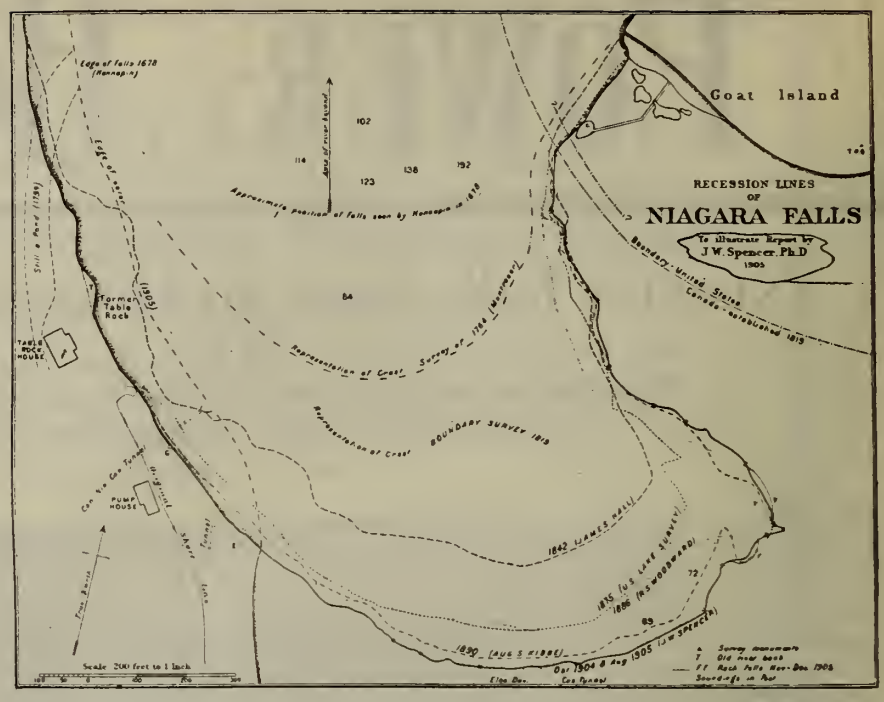

FIG. 1—CHART SHOWING THE RECESSION OF NIAGARA FALLS AT THE END OF DIFFERENT PERIODS OF TIME.

The deep, narrow gorge extending from the Falls to Lewiston is of special interest to the geologist. This canyon is scarcely a quarter of a mile wide and varies little in distance from cliff to cliff throughout the greater part of its course. The walls are so precipitous that they offer few opportunities for foothold, and in height from the bottom of the river vary from two hundred to five hundred feet. If we observe both sides of the gorge we find the same order in the layers of rock and shale on comparatively the same level, with the same thickness of each corresponding stratum. Observing these features we cannot help but conclude that this immense cleft has been worn out by the force of the water from a structure whose features were one time continuous, as is made manifest by the similarity of the exposed strata on both sides of the stream.

To be convinced of the fact that the Falls themselves are gradually receding, it is only necessary that we refer to the various surveys which have been made at different times (see Fig. 2), or we can by observing them closely, witness with our own eyes masses of rock which have broken away and lie in huge broken masses at the foot of the Falls.

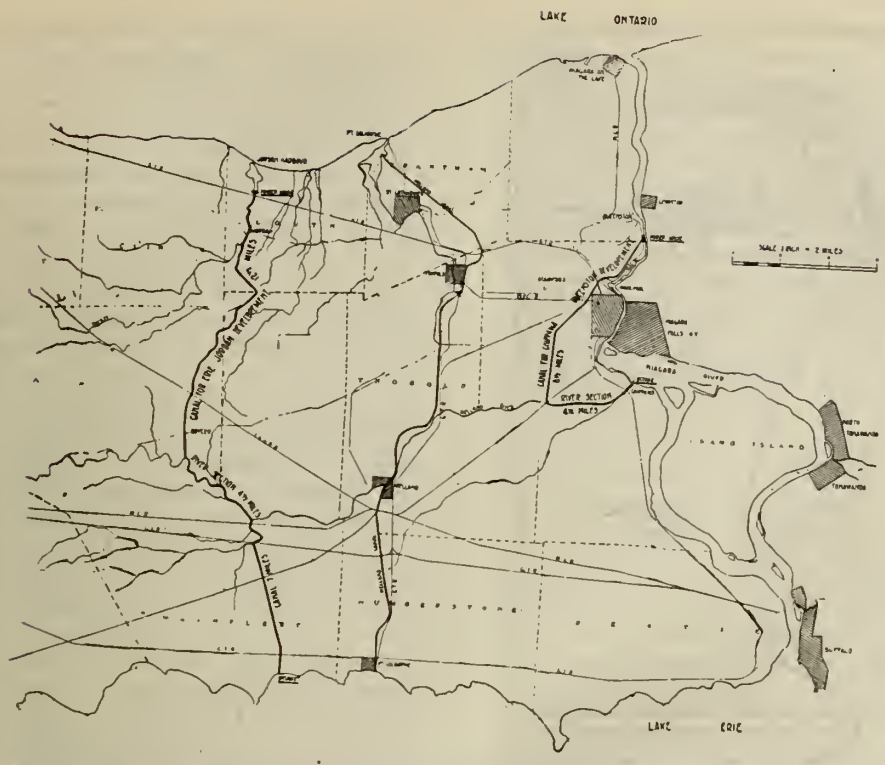
Rate of Recession

Between 1890 and 1905, the Canadian or Horseshoe Falls, according to exhaustive investigations made on this subject by J. W. Spencer for the Canadian Government, have indicated that a mean annual recession of 2.2 feet has occurred during this period, while the recession of the American Falls has been found to be less than 0.60th of a foot per annum.

If we observe closely the violent whirling of the water as it strikes the rocks below the falls and recoils most powerfully against the shale forming the greater part of the surface of the cliff, we see how the soft shale beneath the harder stratum of limestone rock is worn away until the harder surface rock forming an overhanging ledge is broken off by the weight of the water and falling, is in its turn crumbled by the constant action of the falling water and shale until it also is carried away down the river. This is illustrated by Fig. 3.

All this establishes the fact that the gorge is growing longer from its northern end through the agency of the waterfall. We see, therefore, that the river has a big task before it and that its work is only partly accomplished. Two thoughts spring into our minds instantly: When this work is completed, what will be the result, and what did it do before its present work had begun? It is apparent at once that waters of Lake Erie could never have flowed to Lake Ontario without wearing the Gorge as we now see it. The birth of the river and the wearing away of the canyon must, therefore, have been simultaneous

Upon observing a map of the continent of North America, it is noticed that a great difference exists in the appearance of the land surface of the northern and southern sections. From the region of the Great Lakes northward, the district is one continuation of irregular indentations filled with water, forming many lakes and swampy regions. The northern rivers are also filled with many rapids and waterfalls containing undreamed-of potentialities for the generation of hydro-electric power, while south of the Ohio river there are but few lakes and the rivers flow through almost unbroken courses. To the geologist this difference of the earth's surface in-



MAP SHOWING VARIOUS CANALS PROPOSED FOR THE NIAGARA PENINSULA. THAT TO THE LEFT IS THE PROPOSED JORDAN DEVELOPMENT ABANDONED IN FAVOR OF THE CHIPPEWA SCHEME SEEN ON THE RIGHT. THE MIDDLE CANAL IS THE NEW WELLAND NOW UNDER CONSTRUCTION.

dicates that the southern region is much older than that to the north; its waters have had greater periods of time in which to mould down elevations and fill up depressions. This difference in the characteristics of the streams of the north and those of the south is explained by the great ice age.

The Glacial Epoch

There probably was little difference in relief forms between the two sections of the continent before the incroachment of the ice, but during the glacial epoch the whole northern part of the continent was covered with a massive sheet of ice. The ice sheet was continually renewed at the north, and as continually drifted in a southerly direction. As this enormous ice cap passed over the earth's surface it acted somewhat like a river in its erosive power, only working for greater changes in much less time, the whole configuration of the country being thus recast.

Many old valleys were obliterated, while a number of new ones were carved out. A change of climate, which astronomers explain by a gradual change in the earth's inclination to the sun, but which we have not the space at our disposal to describe, occurred, causing the ice to retreat northward as its southern edge melted, and so the new depressions were filled with water, which formed new lakes and rivers, and with the ending of the ice age the history of the Niagara River began.

If we look closely at the map again, we see that a low range of hills form a water-shed between the Great Lakes and the streams flowing to the south.

When the southern terminal of the ice had retreated to the north of this divide but still blocked all outlet to the north or east, there probably were a number of lakes here discharging their waters across the present low watershed to the south . Some of these ancient valleys can still be traced for long distances of their course. These lakes passed through varying changes as have those of the present day, and their waters have left indelible carvings on land surfaces which then formed their shores.

The ice continued its retreat, and we next notice the greatest change in elevation of the surface of the water. The ice finally passed to the north of the present Mohawk River, thus permitting the waters to escape by that outlet, which resulted in a lowering of the surface of the lakes over five hundred feet. Then the Niagara began to flow and its falls commenced their gigantic task.

The ice barrier waters of the lower lakes (Ontario) were as yet discharged near Rome, New York, but finally the encroaching warmth of the south removed the ice barrier which blocked the regions north of the Adirondack Mountains, and the water began flowing by the St. Lawrence course. These variations had a great effect on the work of the Niagara River. When the Niagara River commenced to flow, its terminal, instead of being seven miles from the escarpment, was only about two miles away, and the surface of the lake was about seventy-five feet higher than at present. While the Rome outlet remained the same, the eastern end of the lake was continually rising, thus causing the waters at the western end to rise over one hundred feet. The shore of Lake Ontario was thus placed almost at the foot of the cliff at Queenston. It occupied this position for a considerable period, but finally the waters again fell over two hundred feet, carving another shore line now submerged beneath the waters of Ontario. After this, various changes in the level of the land and shifting of the ice barrier caused numerous old shore lines to be faintly carved. Changes of this nature continued until the present outlet was established and the waters began their flow along the present course of the St. Lawrence.

Let us turn once more to the gorge of the river itself. The similarity of the structure of its two sides has been noted. This similarity is continuous throughout its length except at a point about half-way between Lewiston and the Falls, where the river makes a turn in its course of almost ninety degrees. This point is known as the Whirlpool. On the outside of this angle appears the only place in the entire course where the material of the cliff changes. We find here a break in the solid rock of the bank, filled with loose rock and gravel. This rift is of pre-glacial origin, for it is filled with the same material, the glacial drift covering the whole region. A few miles west of Queenston on the Ontario shore we find a broad gap in the otherwise unbroken wall. This gap is also filled with glacial drift. This buried St. David's Valley has, by sinking well along its course, been traced back to the Whirlpool, and undoubtedly formed the course of some pre-glacial stream.

Later this interpretation was destined to furnish further explanations, for the question at once arose, how far and where did the upper course of this ancient valley extend? If it had cut across the course of the modern river there would have been a break in the continuity of the cliff somewhere on the opposite side of the Gorge; this break, however, was nowhere to be found. The conclusion was therefore reached that the upper course of this ancient channel must have coincided with that of the present channel.

Therefore, when the Falls had receded from Queenston by its present course to the side of the present Whirlpool it reached a point where the greater part of its work had been performed. From here, to whatever distance the upper course of the ancient river extended, the only work it had to do was to remove the loose gravel and boulders with which the glacier had filled its ancient channel. Of course this was effected far more rapidly than the wearing away of the hard limestone bed.

As to just what was the depth and the extent of this old deserted valley, it is of course almost impossible to estimate.

Estimates of Age of Niagara

Thus, the calculations of the age of the Niagara River, made by Andrew Ellicott in 1790 as 55,000 years, by Bakewell as 12,000 years, and by Sir Charles Lyell as 36,000 years, which estimates of the age of the Falls were arrived at by dividing the length of the Gorge by

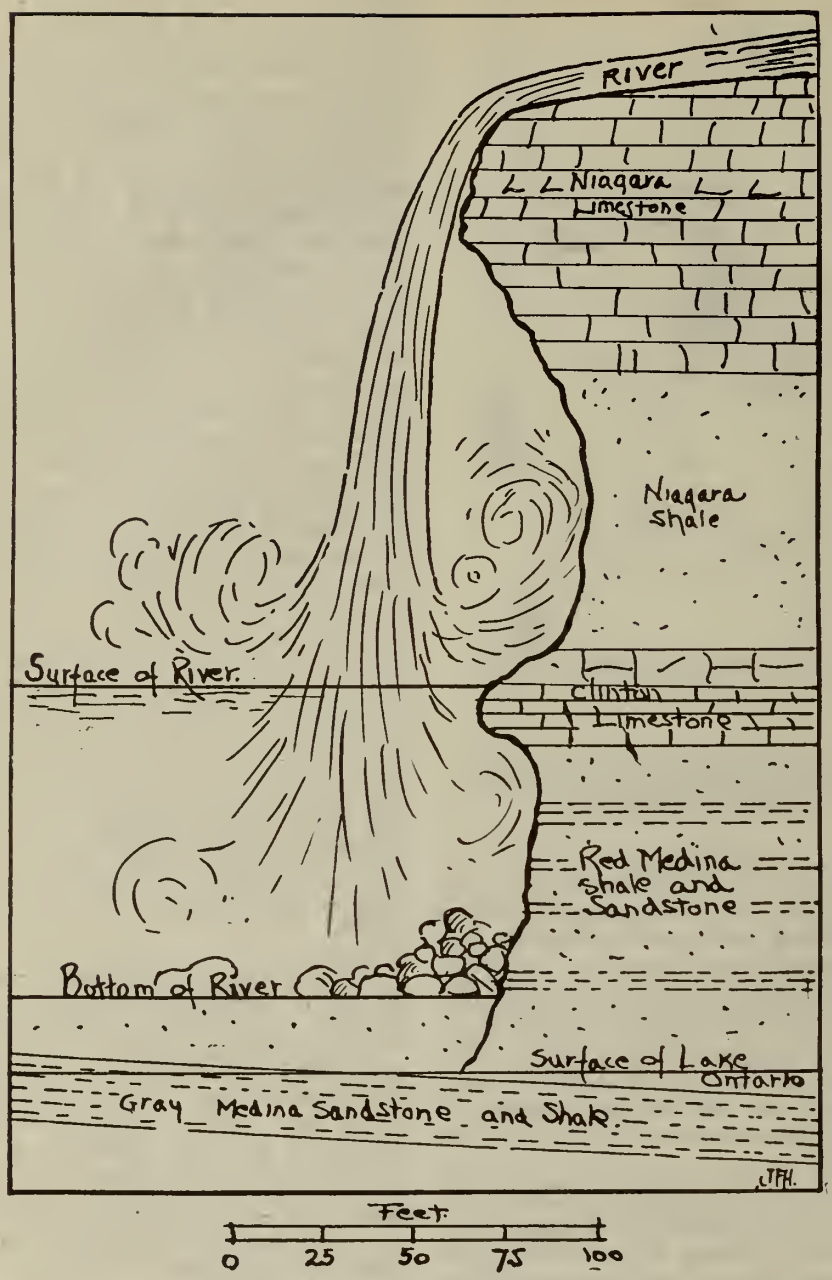


FIG. 3—CROSS-SECTION THROUGH FALLS.

the supposed rate of recession per annum involved certain errors in the rate of movement of the Falls, besides making no allowance for the variations introduced by the discovery of the buried St. David's Channel.

In 1842 Professor James Hall made a survey of the Horseshoe Falls under the authority of the New York Geological Survey. This survey plotted the position of the crest of the Falls and established monuments at the points at which the angles were taken, thus leaving lasting marks of reference to which any future survey might refer. J. W. Spencer, before mentioned, after making a thorough study of the history of the river, revealed in its markings, and also of the lakes, after making allowance for all known variable factors, calculated the duration of each epoch separately and found the age of the river to be about 32,000 years.

Dr. Frederick Wright later on hit upon an entirely different means of calculation, one which seems to be much more free from unknown factors and based upon the rate of enlargement of the mouth of the river at the Niagara escarpment where the Falls first began their existence (Dr. Wright's observations may be read in detail in Archer Butler Hulbert's fine work, "Niagara River"). The cliffs at the mouth of the Gorge, as is the case with the newer portions of the river and characteristic of all canyons when first formed, were undoubtedly almost perpendicular when they were first cut by Niagara's rushing waters. The mouth of the Gorge at Lewiston is of course the oldest part of the modern river, and were it possible to measure the age of this part this would surely give the date of the birth of Niagara.

Just as soon as the Falls commenced their work at Lewiston the waters began the cutting of the Gorge; at the same time as the formation of a gorge began there was set to work upon it walls the disintegrating agencies of the atmosphere, free from indeterminate variables tending to pull down the cliffs up each side of the stream. This work has continued year after year and century after century without being affected by the volume of the river's waters or the shifting in the elevation of the land. This work of the atmospheric agencies in enlarging the mouth of the Gorge has had the effect of changing its shape from that of a rectangle, with perpendicular sides of 340 feet, to a figure with a level base formed by the river, whose sides slope off at the same angle on each side. Were it possible to measure the rate at which this enlargement is taking place the problem of determining the age of the river would be a far more simple one.

Dr. Wright's calculations were taken along the line of the railroad which has been constructed along the eastern cliff. For a distance of about two miles the course of the road runs diagonally down the face of the cliff, descending in that distance some two hundred feet and laying bare in its descent the layers of shale upon which the observations must be made. Along the course of the road at this point, watchmen are continually employed to remove obstructions which have fallen and to give warning of danger when any large masses fall. The disintegration goes on much more rapidly in wet thawing weather than at other times of the year.

Dr. Wright estimates that at the rate of one-fourth of an inch a year of waste along this cliff, taking into consideration its area, there ought to fall slightly over six hundred cubic yards of earth and stone annually for each mile where the wall is 150 feet high. At this rate of enlargement, which is a very conservative one, Dr. Wright estimates that such enlargement would take place in somewhat less than ten thousand years.

The estimate of the annual fall was made from the railroad records showing the cost of removal of the falling matter, together with the observations of the watchmen, one of whom had been watchman at this point for twelve years, and also by measuring the distance to which the cliff has receded since the construction of the road.

Several variables, however, still enter into these calculations, one of them being that when the railroad was built, a fresh section of the shale was presented for the atmospheric agencies to work upon, yet making all due allowances the rate of disintegration at the mouth of the Gorge could not have been much less than that assumed above. From observations made, if the calculations be true, this new line of evidence places the birth of the Niagara and the beginning of the cutting of the George at Lewiston about ten thousand years ago, in fact, the glacial epoch, affirms Dr. Wright, continued down to historical times. The evidence, he believes, is such as should convince anyone who candidly considers all the facts, that glacial ice did not retreat from southern Sweden until seven thousand years ago. Nor did it retreat

from central New York and northern Minnesota at a much earlier date. Even at late as the present day it is still retreating at a rapid rate in Alaska, the Muir Glacier having retired on the average of seven miles and half in the last twenty-five years, and nearly all the other glaciers have retreated proportionately. It would therefore appear that when the civilization of Egypt, Babylonia and Central Asia was at its height, the most populous and progressive present centres of civilization were hidden beneath a tremendous glacial covering.

In concluding our geological observations, let us consider the proximate future of Niagara. The measurements obtained by various authorities concerning the recession of Niagara Falls indicate that there has been some reduction in the rate of recession during the last twenty years. The discharge of the river has been reduced to some extent artificially. The diversion of water for power purposes shows that a pronounced lowering of the upper rapids has taken place and a reduction of flow has been caused to a small extent by meteorological conditions. If the diversion of water for power purposes goes on, as it undoubtedly will, even though this diversion is at present limited by international treaty, generations hence may know of the grandeur of the Falls as a matter of history only. This result, however, may be overcome by the suggestion that the water be turned on for a brief period daily and run through turbines the rest of the time.

It has now been estimated that over 3,000,000 horsepower of energy is flowing to waste at Niagara, a writer in "Engineering and Contracting" (Chicago), whom we cannot help concluding is possessed of a somewhat Shavian humor, estimates that Niagara Falls power is worth to society $50 per horsepower per annum. As about 1,000,000 people view this great "natural moving picture" annually, it follows that each observer is indebted to society for $150 every time he visits the Falls. This writer suggests, therefore, that this great waste be avoided by arranging that for one hour each day the entire volume of water be allowed to flow over the great brink, and for the remaining twenty-three hours the water be run through shafts and tunnels upon turbines. This, he points out, would lower the cost of a look at the Falls down to about $7—the price of three theatre tickets, instead of the price of six suits of clothes.

A further suggestion regarding the recession of the Falls has been made by an eminent engineer who, presuming that the present rate of recession may continue indefinitely, has pointed out that as the Gorge recedes it will drain, as it has hitherto done, the banks to the right and left of it. This will, of course, eventually drain entirely the American branch of the river, the present channel of which will in time become cultivable land, while the American Falls will be transformed into a dry precipice that will then form but a simple continuation of the cliff boundary of Niagara Gorge. The draining of the present banks of the river, coupled with the recession of the Falls will, of course, seriously affect the present power companies' intakes located at various points along the river. The engineer referred to, therefore, suggests that, in order to prevent this taking place, an excavation be made beneath the river's bottom from either bank at a point some distance back from the present brink of the Falls. If this excavation, made to a depth equal to the bottom of the lower river and nearly to the surface of the upper river, be filled with concrete, it will form an effective artificial barrier against any further recession of the Falls when the recession now going on reaches it.

The Latest Niagara Projects

Canada, with her characteristic energy, is starting upon a great enterprise in order that she may, in addition to the power already developed, produce 300,000 additional hydro-electric horsepower from the Niagara River. In order to secure this vast amount of energy she proposes to secure an entirely new effective head of 305 feet (instead of about one-half of this amount as in the cast of the power plants located at the Falls), by constructing this new power plant at Queenston on practically a level with Lake Ontario.

In addition to this project a still larger proposal has been made by the United States. This covers the construction of a combined ship, sanitation, and power canal from Lake Erie to Lake Ontario. Its length would be roughly 40 miles, its depth 30 feet, with a fall of 327 feet. It would be capable of transporting the largest vessels and barges from lake to lake, and it would also divert the sewage of Lackawanna, Buffalo. Tonawanda, and other cities from Lake Erie and the Niagara River, and after purifying it would discharge the waters into Lake Ontario. These waters would also be used to develop 800,000 hydro-electric horsepower. If this splendid project be carried out, it may be expected that the Niagara district, in possession of the cheap power that will be thus made available, will become perhaps the greatest manufacturing centre on the face of the globe. The tremendously beneficial results that will accrue to Canada as a result of this achievement of modern engineering, are scarcely realizable, but doubtless the comparatively near future will find them an accomplished fact.

Those of us, therefore, who have stood in awestruck silence before Niagara's majestic moving flood formed by an accumulation of waters drawn from almost half a continent, may soon recall only in memory the effect of permanence that this mighty fall of water, reborn as it dies, brings to us as we thrill with admiration and delight upon its towering brink.

The passing of Niagara will perhaps also recall to the minds of those who know it best the gradual disappearance also of an inscription to be seen engraven on a rock, but now almost obliterated by the action of the elements, on Luna Island:

"All is change
Eternal progress
No death!"

The author of the sentiment is unknown, but no one has ever more truly voiced the spirit of the great cataract.

FURNACE COLLAPSE DUE TO EXCESSIVE DENSITY OF WATER

Recently an inspector was sent for to report on a severely collapsed furnace. He found no signs of shortness of water, nor of grease, nor a scale, in the boiler. Within a day or two the same firm telephoned that the furnaces of the other boiler had collapsed. We thereupon asked them to draw off some of the water before emptying the boiler, and our chemist visited the works in the hope that he might find the reason for these mishaps. He too could detect no apparent cause for the collapse, but when he asked for the bucket of boiler water of which he wished to bring back a sample, it was found to be almost a solid mass of crystals which, on being analyzed, proved to be sulphate of soda (Glauber salts). It thus appears that the boiler had been working not with water but with melted Glauber salts. This is the well-known salt with which the beautiful experiment on supersaturation is generally carried out.

Comparing this collapse with collapses due to common salt in solution it is quite evident that boiler water may without danger be allowed to contain a much larger percentage of sulphate of soda than of common salt, for, judging by a well-authenticated case of a new boiler of 200 lbs. pressure, collapse took place when the percentage of salt in the boiler water reached 8 per cent. In the present case the percentage of the anhydrous sulphate of soda must have been about 30. No reliable information was obtainable as to whether the steam produced from the melted sulphate of soda was superheated as it ought to have been. The only available information is that the piston rods were frequently covered with salt. —C. E. Stromeyer in Report for Manchester Steam Users' Association.

Belts form a very important part of the equipment of factories—a part of equipment that is habitually used, however, in most inefficient and wasteful manner. There are exceptions, notably in connection with the more modern machinery. But many belts are running at an average speed of nearer 1,000 than 4,000 or 4,500 feet a minute. As a result six-inch belts are used where one-and-a-half or two-inch belts would be not only much cheaper in first cost but also much better. Bearing pressures are materially lessened, while friction and the accompanying wear and power consumption are reduced. This tends to conserve leather, fuel and oil, and lower repair expense.

Water Softening and Purifying Processes

It is Much Better to Keep Scale Forming Materials Out of the Boiler Than to Use It as a Medium for Carrying on Chemical Reactions. The Following Article Deals With Some of the Purifying Processes Used

By C. E. STROMEYER

THE Permutit process is based on a selective action possessed to a small degree by all chemical compounds, and which is very strongly marked in a few. In them chemical changes are affected by the relative solubilities of these chemicals. A few natural minerals of this class are known as zeolites, and are similar to the artificial permutit, which has the following composition: 2 SiO_2 (Silicic acid), Al_3O_6 (ammonia), a loosely-held base and 6 molecules of water. Let it be assumed that the loose base is soda, sodium oxide, then, if a solution of a calcium salt, for instance bi-carbonate of lime, be passed through the permutit, the sodium oxide is exchanged for the calcium oxide, the former combining with the carbonic acid to form bi-carbonate of soda. If now we pass a solution of common salt (chlorine of sodium, NaCl) through the changed permutit it parts with its calcium, and again takes up sodium. But this second reaction takes place the more readily the greater the relative strength of the dissolved sodium salt to the dissolved calcium salt. This means, that whereas sodium permutit will extract all the calcium out of a solution with which it is brought in contact, calcium permutit will not act in the reverse sense and extract all soda from its solution, unless the solution is practically free from calcium salts. This means that the salt solution with which the permutit is regenerated ought to be as pure as possible. Thus, for instance, the output of a permutit softener is nearly doubled by using pure salt instead of rock salt, or natural brine.

The softening procedure therefore consist in passing the hard (lime) water through the permutit whereby all the hardness is readily removed, and then indulging in a regenerating process by passing an excess of a solution of common salt through the permutit. It is, therefore, evident that more salt must be used than the equivalent of the lime contained in the untreated water. It also follows that the treated water will contain an equivalent amount of sodium bi-carbonate or sulphate, as the case may be, for the amount of lime removed. This process, therefore, although it removes all the lime, can therefore produce a water which is perfectly soft and suitable for almost any washing and dyeing process, yet it adds soluble salts, which, if the untreated water was very impure, would soon accumulate in the boiler and necessitate blowing down at certain intervals.

A very serious objection to the adoption of this process is the expense of working it, for every ton of lime to be removed requires two tons of common salt. The process is therefore sometimes modified in practice by firstly reducing the hardness of the natural water to a few degress by the ordinary lime and carbonate of soda process, and then treating it with permutit. About 5 per cent. of permutit is lost per annum, due to the purifying and regenerating operations. The speed with which the feed water is passed through permutit should not exceed 12 ft. to 15 ft. per hour. This speed fixes the diameters of the permutit tanks.

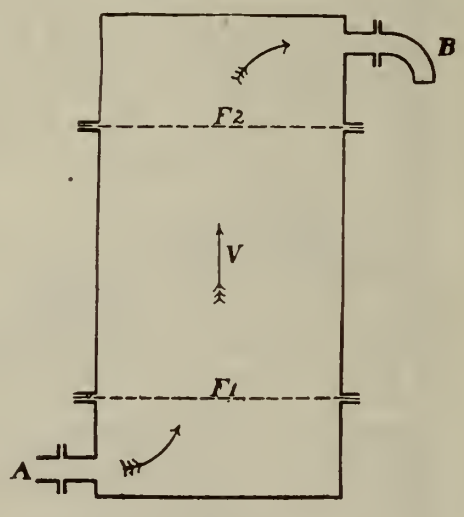

FIG. 1.

The Chemical Process of Water Softening

Before discussing the principles of sedimentation and filtration it will be well to deal with the incompleteness of chemical reactions, more particularly as this subject is related to the chemical action of permutit.

It is well known that if a carbonate of soda solution be brought into contact with sulphate of lime, an exchange of acids takes place, the carbonic acid of the soda passing to the lime salt and its sulphuric acid passing to the soda. But the process is not a perfect one, a trace of sulphate of lime remaining in solution even when there is an excess of carbonate of soda. This and many similar incompletenesses of chemical reactions are well known to chemists, and their laws have been formulated, but there is great uncertainty as to the relative affinities.

In order, however, to obtain some information as to the limits to which water softening processes can be carried, the two following experiments were made:

First experiment.—Assume that a softening reaction has been carried out, that sulphate of lime (permanent hardness) has been converted into carbonate of lime (temporary hardness), and that all the carbonate of soda used in this imaginary softening reaction has been converted into sulphate of soda. Chemically pure carbonate of lime emulsion and sulphate of soda solution were now tested for alkalinity and mixed together, when it was found that the alkalinity of the mixture had increased by an amount which corresponded to a reversal of the imaginary softening process to the extent of 2.43° of hardness. This then seems to be approximately the limit to which the softening of permanent hardness can be carried, though it will be materially affected by any other salts which may be present in the treated waters.

In the second experiment carbonate of lime and sulphate of magnesia solutions were mixed, and again a slight reversal of the chemical reaction took place corresponding to 3.26° of hardness.

In addition there is the slight solubility of carbonate of lime which at ordinary temperatures is equal to about 2.4° of hardness, but this is easily exceeded if carbonic acid has access to the water.

Thus these experiments seem to indicate that the ordinary softening processes cannot reduce the real hardness below 2.4°. These laboratory experiments are in agreement with practical experiences, it being found impossible to remove all hardness by the ordinary softening reactions. "Hardness" here means actual contents of lime and magnesia salts.

The time factor also plays an important part in water purification. Thus assuming that the impure water and the chemicals are merely turned into a channel which conducts them into a tank, it is quite conceivable that the desired intimate mixing does not take place, and if the reaction tank be small, some portions of the two fluids will not have met at all, a certain amount of hardness will remain in the water, and the process will only be completed in the boiler, where long-continued intimate mixing takes place, instead of in the water purifier. Possibly the reaction tanks might become more effective if the two fluids were to be thoroughly mixed the moment they are brought together. Very effective mixing is effected in some

chemical processes by passing the two fluids through a channel shaped like Row's tube, i.e., a tube flattened at successive points, intermediate flats being at right angles to the two adjoining ones.

However, even when perfect mixing has been effected between two fluids, chemical reaction requires a certain amount of time before it is completed, and much research work is now being devoted to the subject, though numerical results are scarce as yet.

One of the best illustrations of the slowness of chemical reaction is afforded by the developing process of photographic plates, which extends according to circumstances over one to 10 minutes. The chemical process of water softening is much slower than this one, but, like it, it can be accelerated both by heat and by agitation.

The Archbutt-Deeley process takes these factors into account, for the water and chemicals are both heated and agitated while the chemical process lasts. This process also takes account of the fact that the conditions which are favorable to the chemical reaction, especially agitation, are unfavorable to the settlement of the sediments, and in this process the chemical reaction and the settlement are separated by a time interval. In nearly all other processes the desire to save space had led to merging the chemical and the settlement conditions, and although the results are in many cases favorable, the margin between success and failure seems to be far too narrow, and it is more than likely that even better results than those obtained up to the present might be achieved by separating the two processes more completely.

In order to be able to judge of the merits of the several types of water softeners, it is desirable to bear in mind not only the limitations of the chemical processes, the necessity for intimate mixing, and the slowness of the reaction, but also the leading principles of filtration and sedimentation. They may at the very start be summarized by saying that it is desirable to make the particles of sediment as large as possible, for if the water is to be filtered it is evidently a very great advantage to have coarse particles. If the desired coarseness cannot be attained, the filtering fabric must have finer meshes than can be produced in practice, but the apertures can also be reduced by partially choking them with coarse sediment particles. This means that if all the particles cannot be made so large that they will not pass the filter, they should be associated with larger particles which choke the fabric sufficiently to prevent finer ones from passing. The same object is attained by using sand filters in which the finer particles take the place of coarse sediment particles. Mattress filters act by offering a very large rough surface for the adherence of passing particles.

Now the slower the chemical process, the higher the temperature at which it is carried out, and the more violent the agitation of the water under treatment, the larger will be the sediment particles. All these conditions are aimed at in the Archbutt-Deeley process, with this addition, that old sediment, which is naturally of a coarse nature, is mixed with the new sediment and helps to increase the size of the particles. In continuous processes this object cannot easily be attained, more particularly if, as is generally the case, the attempt is made to save space by merging the chemical into the precipitation or filtration process. For instance, if the tank in which the chemical reaction is mainly carried out should be barely large enough for its purpose, the final chemical reaction, which naturally produces the very finest particles, takes place either in the filter or in the sedimentation tank, and these very fine particles have a very good chance of escaping with the treated water into the boiler.

There are two principles on which particles can be removed from fluids. Both are based on the fact that particles which are heavier than water will sink in it with a definite velocity, depending firstly on the excess density over that of water, and secondly on the sizes of the particles.

The velocity with which similarly-shaped bodies of equal density sink through water is roughly proportional to the square root of the dimensions. Thus a flake of sediment of 1-100 in. largest dimension would sink twice as fast as a particle of 1-400 in. length, although it would be 64 times as heavy.

Conversely a very slight change of speed will very materially affect the sizes of the retained particles, and therefore also the perfection of the purification process. This explains why eddying currents in settling tanks should be avoided as much as possible.

The ideal conditions for this process are sketched in Fig. 1. The chemical process is supposed to have been completed, and the treated water enters at and passes through a filtering fabric F_1 in order that the upward velocity V may be uniformly distributed over the section of the tank. The fabric F^2 prevents the discharge at B from creating local eddies. As long as the velocity V is constant, particles of a certain size will tend to remain stationary, neither rising nor falling, but gradually they will draw together to form larger particles and sink But, as this is of importance, all those particles whose downward velocity is less than V, the average upward velocity of the water, will be carried over with it. In this clarifying process it is, therefore, very essential to complete the chemical process before entering this tank and to adopt every possible means for producing the coarsest possible particle.

No attempt has been made either in this or the next diagrammatic sketch to show how the sediment might be removed.

In Fig. 2 the treated water passes from the trough T^1 through a filtering fabric, which gives it a uniform velocity, before it passes across the tank through another filtering fabric to the discharge trough T^2. Now no matter how small the suspended particles may be, if only they are heavier than water, they must of necessity sink if the water has no upward movement, and by making the section of the tank large and the velocity V of the water small, we can ensure that all the water above the slanting line T'a is absolutely free from particles, the coarser ones falling down at b, c, d, etc. The reason why filtering fabrics are shown is because if there were merely weir overflows at T^1 and T^2 a considerable addition would have to be made to the length of the tank in order to get out of the region of local eddies.

Indications are noticeable in many water purifiers that the above two principles have forced themselves on inventors, but apparently the desire to save space has in most cases led to a merging of the chemical and the filtering processes.

There are, however, a few processes, those known as the Boby and as the Lawrence purifiers, in which purification is mainly effected by the application of heat, and the problem of removing the sediment is then very different from the above.

Approximately 400 water softeners have been installed in works of our members, and on the whole we have received few complaints. A few of these were due to wrong instructions, but as a rule inattention was the chief cause of trouble. It was, therefore, decided that our chemist should make a careful examination of a number of water softeners which had been in use for some time.

There are at present 20 different patterns of water softeners, of which half-a-dozen or more are in use amongst our members, and about 25 other patterns of which less than half-a-dozen have been installed by our members. The first lot includes the following, arranged alphabetically: Archbutt-Deeley, Bell, Boby, Criton, Crossfield, Desrumaux,

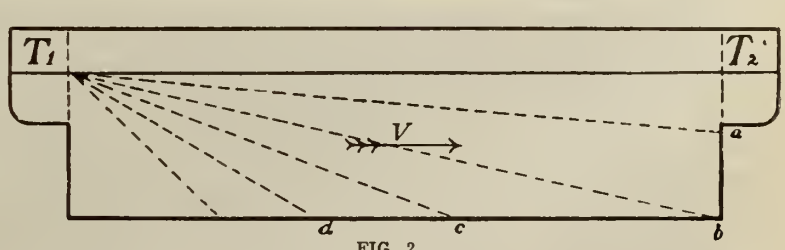

FIG. 2.

Doulton, Guttmann, Harris-Anderson, Kennicott, Lassen & Hjort, Lawrence, Maigneu, Paterson, Permutit, Porter-Clark, Reisert, Stanhope, Tyache, Wollaston.

With the exception of the Archbutt-Deeley softener, in which the chemical reaction and settling operation are separated by a time interval, the other softeners are all continuous, and in most cases, too, the chemical reaction continues as far as the settling tanks and sometimes even as far as the feed pipes and the boilers, as is proved by the deposition of scale in these parts. In the Boby and in the Lawrence softeners the chemical reaction is supplemented by, and sometimes entirely replaced by, heat reaction, and sometimes these so-called detartarisers are added to other softeners. The only softener in which the principle illustrated in Fig. 2 is made use of is the Desrumaux softener, the horizontal tank being replaced by a helix. All the other softeners use the principle illustrated in Fig. 1, the differences between them being confined to the appliances for adding the chemicals. These, however, are of comparatively little importance if the flow of the water through the apparatus is too rapid and the times allowed for reaction, settling, and filtering are kept too short. Thus in some softeners which were inspected by our chemist the upward velocity was as high at 20 ft. per hour, in others as low as 2 ft., which means that in the first-mentioned case the weights of the particles carried over with the treated water would be about one million times greater than those carried over in the second case. No wonder, therefore, that in the first set of cases there would be complaint about the feed pipes choking and floury deposits forming in the boilers and being carried into the steam pipes and even into the turbines.

The information gained by these inspections was of great value, but it cannot be detailed here as it would consist to a large extent of criticisms of details for which the makers are responsible, including instructions about the chemical reagents, which are not always quite correct. But most of the troubles met with were due to inattention on the part of the attendants.

There is, however, one point to which attention should be specially drawn—the tendency in some cases for softened water to cause corrosion, usually of a local character. In these cases the water contains salt, and, as is now well known, the combination of salt and soda along with dissolved air tends to cause pitting of boiler plates. The reason for this behaviour is as yet not fully understood, but it is known that whereas soda solutions will rapidly polarize iron surfaces, salt solutions will depolarize them, and it is possible that when the two salts act together they cover the iron surface with alternating patches of polarized and depolarized iron which, when in company, of course act as powerful galvanic batteries and cause local corrosion of the depolarized area. Good preventatives are a slight excess of soda or the addition of tannin solutions. The latter must, however, be added to the feed after, and not before or during the softening process, otherwise the tannin is precipitated and removed in the filters before it can do any good.

In view of the injurious effect of salt and soda combined, all those boilers which are supplied with feed water which has been treated with permutit were reviewed, because here, the regenerating fluid being brine, and carbonate of soda being in solution in the softened water conditions for pitting seemed to be favorable, but in none of these cases did our inspectors detect either pitting or local corrosion. Possibly, therefore, the pitting process is not such a simple one as that suggested above.

The Lawrence water softener is still called a sterilizer, because it was at first used only for sterilizing purposes. It is based on the counter-current principle, and may be illustrated by the movements in a Field tube. The untreated water passes along the inner tube and flows out through the annular space between the inner and outer tube. The extreme end of the tube is heated to any desired temperature, and as the heated water passes along the annular space it parts with its heat to the incoming water in the inner tube and leaves the apparatus at a temperature which is only slightly in excess of that of the supply. This difference can be reduced to 20° Fah. or even 5° Fah., if the heat-exchanging surface be made large enough, so that although the water may be raised to 212° Fah., or even converted into steam and recondensed, which process represents a heat exchange of about 1,000 B. T.U., the actual loss of heat need only be 5 to 20 B.T.U. Such an arrangement is, of course, a very economical one if the water has to be cooled down to ordinary temperatures after sterilizing, but there is no need to adopt this refinement when it is desired to supply warm water to the boilers Consequently in the Lawrence feed-water softeners the counter-current arrangement is of secondary importance and special attention is devoted to suitable arrangements for dealing with the sediment which is formed when the water is heated.

If the principles on which this sterilizer is based were carried to extremes an apparatus would result which seems to have been invented several times and forgotten again. The oldest record is a Viennese invention, then followed a French and a Belgian one. Instead of merely heating the water, it is actually evaporated and recondensed before it passes along the heat-exchanging surface. The apparatus might be conceived as being of the same design as an ordinary evaporator, i.e., a vertical cylindrical vessel with a lower and an upper chamber connected by a number of heat-exchanging tubes. The cold water enters the lower chamber and slowly rises in the tubes to a suitable height, its temperature being gradually raised by the condensed water around the tubes, which travels downward with an equally slow motion and is drawn off at the bottom. A pipe leads from the upper chamber to the middle cylindrical space around the tubes. Into this connecting pipe there must be fitted a compression pump, or fan, or an ejector, which will produce a partial vacuum over the incoming water and a slight pressure in the cylindrical vessel around the tubes. The power used for driving the compressor or ejector is converted into heat, and is finally carried away with the distilled water and as radiation. Assuming that these devices create a difference of pressure of say 6 lbs., the steam and water around the tubes will be 18° Fah. hotter than the water in the tubes, which will. therefore, be evaporated, pass through the compressor or ejector, and be condensed in the cylindrical vessel and cooled as the condensed water sinks lower and lower, the differbe 18° Fah. being maintained to the end. Under these circumstances the heat required for distilling and recondensing 1,000 gallons of water would be 180,000 B.T.U., or about as much as could be got out of 20 lbs. of coal in an ordinary boiler, which is a ridiculously small quantity compared with the total exchange of heat. As the heat transmission through a metal plate is about ½ B.T.U. per second per square foot for a difference of 18° Fah., and as the total heat transmission for the evaporation and condensation of 1,000 gallons is about ten gallons, it follows that if we should wish to produce 1,000 gallons of distilled water per hour the heat exchanging surface would have to be nearly 5,000 sq., ft. If we double the difference of temperature from 18° to 36° Fah., the surface could be reduced to 2,500 sq. ft. A very simple calculation could, therefore, be made to show which temperature difference should be adopted in order that the interest and depreciation of the apparatus, plus the cost of fuel, would be a minimum. The trouble with these distillers seems to have been the removal of the scale and sediment.

The subject of water purification would be incomplete without a brief reference to barium aluminate, which, like caustic lime, removes temporary hardness without adding more soluble salts to the water, but it differs from lime in that it leaves no residual hardness of 3 or 4 degrees, and is, therefore, almost as effective as distillation. It is however, associated with the drawbacks that barium salts are poisonous and not easily procurable at present.

Railway Converter Substations—Part I.

The Author Gives Some Useful Information Concerning theClass of Equipment to be Used and Its Arrangement in the Substation Buildings

By C. F. LLOYD, Manager Sub station Section, Westinghouse Electric and Mfg. Co., Pittsburgh

DIRECT current railway substations are essentially very similar, since they all perform the same general functions, that is, supply power to propel cars and at the same time provide for safety, convenience of operation and economy. Necessarily, various substations differ widely in arrangement in details to best meet various local conditions.

The rotary converter is generally applicable and preferable to other classes of converting apparatus for railway service, requiring 600 and 1200 volts D.C. This statement is made unreservedly, since the converter has proven its reliability from an operating standpoint while its efficiency, including transformers, is from five to eight per cent. better than that of a similar motor generator without transformers. In cases where a motor generator requires transformers, a greater efficiency advantage is obtained from the converter outfit. The railway substation, at least for interurban work, operates at comparatively poor load factor and in consequence, a further advantage is gained with the converter outfit, since a greater saving in efficiency maintains at the lighter loads. Practically the only conditions which may preclude the use of the converter are two in number, as follows:—

First—Where alternating current feeder line conditions are very poor, having, for instance, excessive ohmic drop, severe surges, wide frequency fluctuations, etc., on which synchronous apparatus would probably prove unstable, the induction motor generator is the proper application. To-day, this application is rarely met, since a system to be consistently efficient must afford alternating current lines with comparatively little loss and be comparatively free from frequency variations, surges, etc. The choice in converting apparatus, therefore, usually narrows down to synchronous motor generators, or rotary converters.

Second—Where the line power factor is very poor it may be desirable to raise it with the converting apparatus, operating partially as a condenser. As the rotary converter is purely a unity power factor machine, a separate condenser is required to produce the same results as a synchronous motor generator, having its motor designed to operate partially as a condenser. Where the first cost and efficiency of the converter, with separate condenser, are equal to or better than the first cost and efficiency of the motor generator, the former is preferable.

Transformers

The type of transformers selected depends almost entirely upon local requirements. The oil-insulated, self-cooled transformer is most universally used, especially in the smaller sizes on account of its simplicity, due to its not requiring any additional apparatus for cooling purposes. If water is to be had in sufficient quantity at little or no expense, it may become desirable to use the oil-insulated, water-cooled transformer, except in the smaller sizes where this type of transformer is more expensive than the self-cooled. In some localities, fire insurance rates are considerably reduced where transformers do not require oil. In cases of this kind, assuming moderate voltages, not to exceed 33,000 volts, the air blast transformer is used. This type of transformer may also be applicable and desirable in large sizes, from a cost standpoint, even though there is nothing to be gained by lower insurance rates. It is, however, a safe rule to

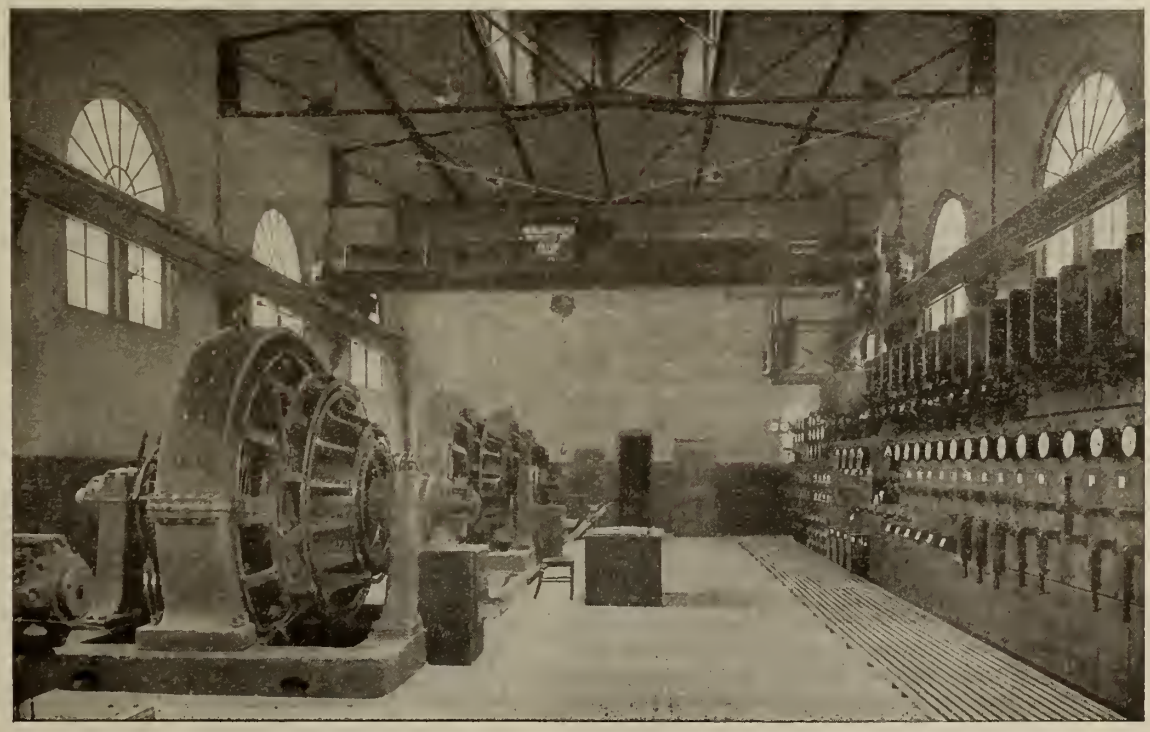

FIG. 1.—FOUR 1,000-K.W. 600-VOLT, 60-CYCLE WESTINGHOUSE RAILWAY CONVERTERS INSTALLED IN PITTSBURGH.

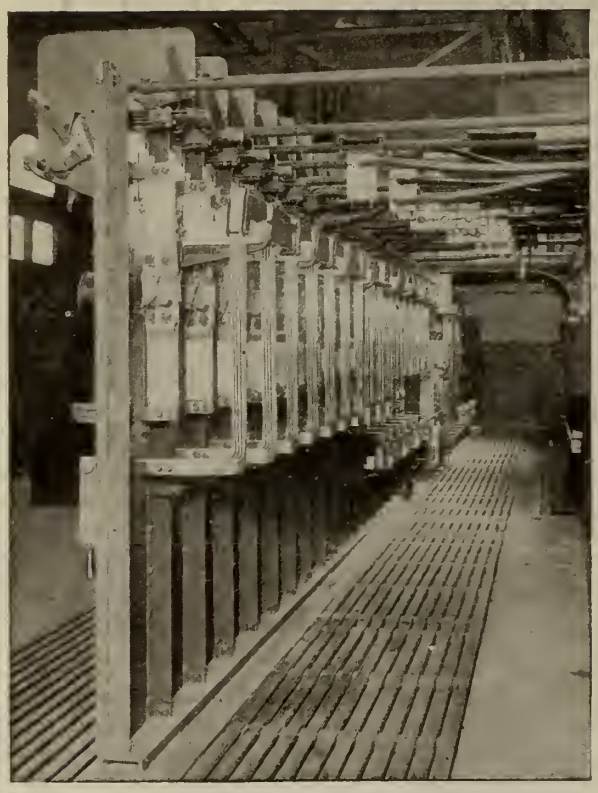

FIG. 2—D.C. SUB-STATION SWITCHBOARD, REAR VIEW.

use oil-insulated, self-cooled transformers, unless some marked advantage is to be gained, such as lower first cost or reduced insurance rates, by the use of one of the other types.

The place selected may be dicated by local conditions. However, since the stationary transformer is possibly even more reliable than the rotary converter there is little to be gained by the use of single-phase in preference to three-phase transformers, unless the first cost is equal or less. Roughly, in the self-cooled type, there will be a saving in the three-phase transformer in voltages below 33,000 for converters up to 1,000 k.w. capacity. Above this size, single-phase are practically no more expensive than three-phase transformers and are, therefore, recommended. In the oil-insulated, water-cooled and air blast, the three-phase transformer is always less expensive.

Reactance, either inherent or external, to their transformers is required by compound railway converters for compounding purposes. Transformers with inherent reactance are recommended in preference to those with normal reactance and external reactance coils primarily due to lower initial cost.

Switching

Upon the selection of switching equipment very often depends the success or partial failure of a substation. The switching equipment must be selected with a due regard for maximum simplicity, convenience and reliability. While essentially standard switching equipment is applicable in practically every case, there are very often local conditions which warrant and require additional protective apparatus for the best results. There is no universal rule to follow in the selection of switching equipment. It can only be selected by competent engineers after careful study of individual local conditions.

A. C. circuit breakers must be selected not only of sufficient ampere capacity, but must be capable of rupturing the maximum capacity available under short circuit conditions. The possibility of short circuit trouble between the high tension breaker and the low tension side of the converter is very remote; in fact, so remote that protection for such an occurrence is not recommended. Consequently the impedence in the converter transformer should be taken into consideration in figuring the current under short circuit conditions. Assuming, therefore, the standard converter transformer having 15 per cent. inherent reactance, the maximum line current that can be taken by a converter operating from this transformer under short circuit conditions will be approximately seven times normal. Therefore, a breaker capable of rupturing seven times normal three-phase line current is recommended for the standard transformer and rotary converter outfit.

D.C. circuit breakers and switches are rated on the basis of the maximum current they will carry for one hour or more, not to exceed temperatures approved by the underwriters. Since standard converters are rated on the basis of 150 per cent. load for two hours, the rating of the circuit breakers and switches should correspond to this value. The calibration range of the D.C. breakers should be considered, as it is good practice to set the machine breaker, where automatic, comparatively high with the feeder breakers set as low as practicable.

A.C. and D.C. meters should be carefully selected to meet the particular application requirements. A D.C. ammeter scale equal to the momentary swing capacity of the converter is recommended. It may, however, be desirable to shorten this scale in some cases in order to obtain better readings on average loads.

Protective Devices

Protective devices as follows are recommended for all installations, if the best results are to be obtained:—

1—A.C. machine breaker with low voltage release and pallet switch attachment.
2—D.C. machine breaker with low voltage attachment.
3—Reverse current relay.
4—Reactive factor meter.
5—D.C. feeder breakers.
6—D.C. feeder resistance.

Adjustment of protective devices is recommended as follows:—

1 (a) The alternating current machine breaker should be automatic. At least in sizes of 1,000 k.w. and below, this breaker should entirely protect the converter from excessive swing loads, and in consequence, should be equipped with an instantaneous trip. In general this will require a high setting, it being satisfactory to work

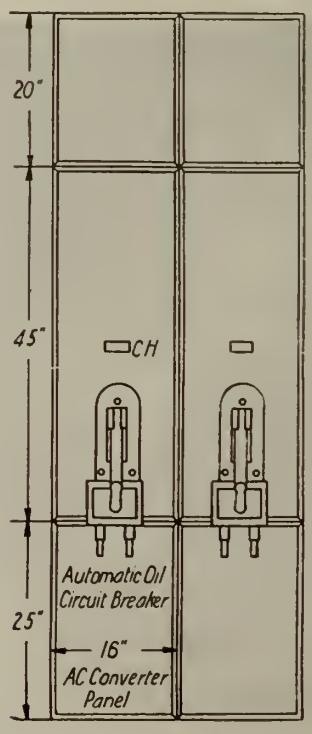

FIG. 3—STANDARD A.C. ROTARY CONVERTER PANELS.

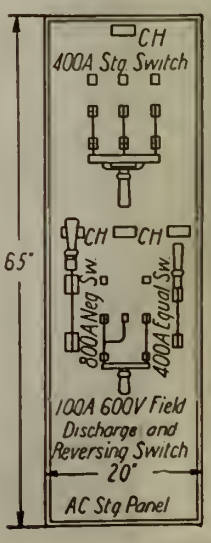

FIG. 5—A.C. STARTING PANEL.

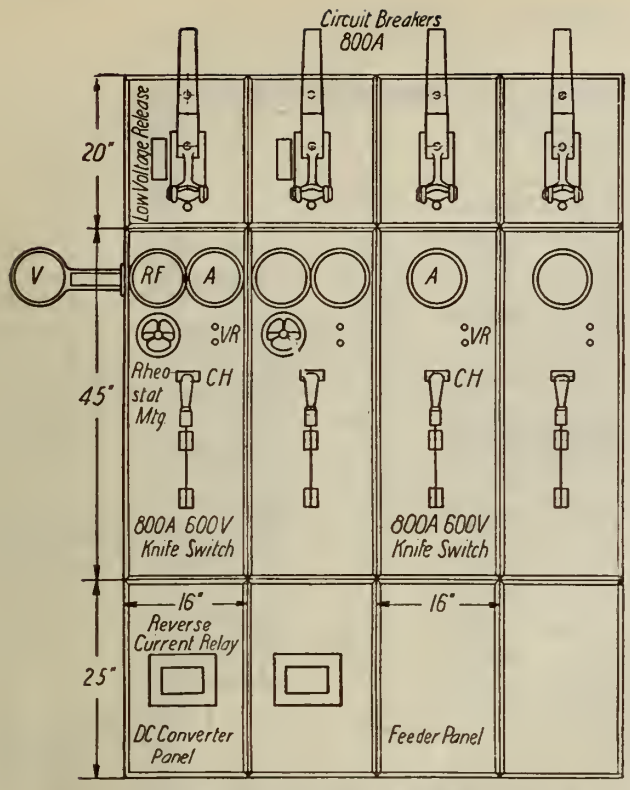

FIG. 4—STANDARD D.C. MACHINE AND FEEDER PANELS.

at any value within the guaranteed swing capacity of the machine. In sizes larger than mentioned above applications may require definite time or inverse time limit trip, which may be entirely satisfactory.

(b) The pallet switch should connect the alternating current and direct current breakers electrically in a manner to cause the direct current breaker to open upon opening the alternating current breaker. The speed limit switch is connected in series with the pallet switch, which also opens the direct current breaker upon operating.

(c) The low voltage release should be adjusted to operate at as high a voltage as is practicable for the application. It is essential, especially for commutating pole converters, to disconnect them from the line when the alternating current voltage drops an appreciable amount, since the restoration of the normal voltage presents conditions similar to switching the converter from the starting to the running position in starting with its trouble, and the nearer the converter and the alternating current capacities agree, the less serious will be the damage resulting from trouble.

2. Capacity of converting apparatus—The larger the converting apparatus, the less sensitive it is to D.C. line troubles, since for instance, feeder short circuits are a smaller proportion of its capacity, and therefore, the machines are less subject to flash-overs from this cause, at least.

3. Voltage of system—The lower the voltage of a given system, the nearer the taps may be placed to the machines. In general, on a given system, tap distance for 1,200-volt service, should be at least twice those of 600-volt service.

4. Size of feeders—The larger the feeders, the greater the tap distances should be from the machines.

5. Disposition of feeders—When possible, the distribution of feeders should be such, that each will carry a reasonable proportion of the station output: that is, where several feeders originate in one station, no excessive proportion of the station output should be handled over any single feeder. Any trouble on such a feeder reacts on the entire substation and is frequently responsible for flash-overs.

6. Size of rails—The heavier the rails, obviously, the greater should be the tap distances.

7. Bonding—Broken bonds and poor ground connections have been known to result in flash-overs. Such cases, however, are not frequent. Obviously, the bonding has a direct bearing on proper tap distances.

8. Sizes of cars—It is evident that with a given substation unit, the heavier the car equipment and the larger the motor rating, the greater will be the "drag" on the substation equipment and the more destructive the effects in case of motor troubles. The rating of the car equipment had, therefore, a bearing on the proper tap distances, especially when the substation units are relatively small, as compared to the motor ratings.

From the foregoing, it will be seen that to evolve a formula to cover such a diversity of conditions would prove itself a problem, and the results, until proven, could not be accepted as much more reliable than a guess. In general, experience has shown that on 600-volt systems, the first tap should not be nearer the machine than 2,500 feet, and on 1,200-volt systems, 5,000 feet. Should flashing persist, these distances should be increased until the flashing stops. The line losses due to these tap distances are of little consequence when compared to the loss on account of flash-overs, including the time and expense involved in cleaning up the damaged apparatus. Furthermore, the car equipment is benefited by being worked at a more uniform voltage.

Rotary Converters Standards

All standard ratings consist of single units, except the 1,200 and 1,500-volt 60 cycle ratings which consist of two machines, each wound for 600 or 750 volts, mounted separately or on a common bedplate, insulated and arranged for series operation. The following table shows the ratings that have been standardized:

Table of Standard Ratings

60 cycle				25 cycle		
Kw.	Volts	Volts	Volts	Volts	Volts	Volts
300	600			600	1,200	1,500
500	600	1,200	1,500	600	1,200	1,500
750	600					
1,000	600	1,200	1,500	600		
1,500	600			600		
2,000	600			600		
3,000	600			600		
4,000				600		

Ventilation

Railway converters are usually designed after careful study of the ventilation problem. It is particularly important on machines for this class of service, since they are often from necessity called upon to deliver very heavy sustained peak loads, which is possible only on well ventilated machines that quickly and efficiently radiate the increased heat generated if they are not to become dangerously hot. Further, the very open construction with thin copper cross sections, especially in field winding, necessary to obtain maximum ventilation, makes it possible to observe accurate temperatures and to know how hard the machine can be worked in emergency.

Starting

Rotary converters are suitable for either alternating or direct current self starting. The alternating current self starting method is recommended on account of its simplicity, due primarily to the elimination of synchronizing. The objection on account of excessive starting Kva required is practically eliminated, due to larger capacities behind the machines and because the self starting machine as now built requires very low starting Kva. The Westinghouse Co. accomplished this by the use of a very effective cage winding located in the pole faces. The efficient manner in which the copper of this winding is distributed over the pole faces renders it, if possible, a more efficient damping winding, which is the heart of stable operation, incidentally meaning successful and reliable operation. The shunt field is controlled by a two-pole, double-throw field switch, with discharge clip and resistance, by which the polarity is reversed when necessary, usually mounted

on the A.C. starting panel. During starting, the field switch should be in the closed position, thus short circuiting the field through the armature. This method of handling the shunt field not only reduces the strain on the field insulation over that obtained with the old field break-up switch with its unsightly frame wiring, but is a great convenience to the operator in starting machines quickly.

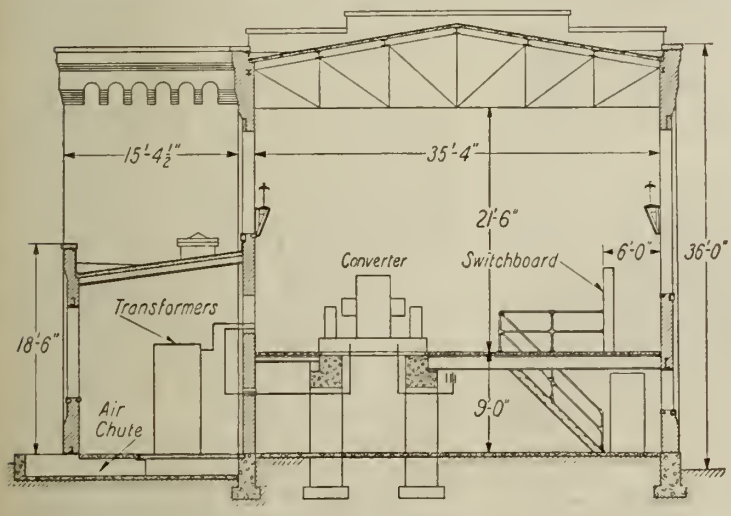

FIG. 8—CONVERTER AND TRANSFORMER ROOMS—ELEVATION.

Ratio of Conversion

Theoretically, there is a fixed ratio of conversion in rotary converters from alternating to direct current. While practically this is true, even duplicate machines may show a slight variation in ratio, due to inequality of material and allowable difference in commercial manufacture. The ratio of conversion remains practically constant, regardless of the load, neglecting a small inherent drop in the machine, and consequently, any change in direct current voltage must be obtained by a change in the alternating current voltage applied. The following table gives the theoretical ratios of transformation in converters:

Ratios of Direct Current Voltage to Alternating Current Voltage in Converters

Phase of Converter	Assuming the D.C. Voltage to be 1.00 Alternating Current Voltage Will Be
Single Phase	.707
Two Phase	.707
Three Phase	.615
Six Phase Double Delta	.615
Six Phase Diametrical	.707

Dominion Waterpower Bill is Explained

Applies to Waterpowers on Lands Administered by the Department of the Interior in the Prairie Provinces, Northwest Territories and Parts of British Columbia Railway Belt

THE following general explanation of the Dominion Water-power Act, which passed its third reading in the House on May 19, is furnished by the Department of the Interior.

The existing legislation affecting water-powers of the Dominion, is contained in a few very general paragraphs of the Dominion Lands Act (Section 35). This section was enacted in 1908 and amended in 1914.

In the course of experience, especially during recent years, this legislation had been found to be inadequate, and it has been difficult for the Department to effect a wholly satisfactory administration of the important water-power resources of the western provinces.

While there is no radical departure from principle, in this Bill, from the very limited treatment given the subject in existing legislation, it has been found desirable to set out the general fundamental principles governing the administration of such an important asset as water-power, in an independent Act, which will leave no doubt concerning the intention of Parliament on any phase of the subject.

The Bill applies to water-powers on lands administered by the Department of the Interior in the Prairie Provinces, the Northwest Territories, and to parts in the British Columbia Railway Belt.

Briefly, this Bill provides:—

(1) That all land and water necessary for power development purposes shall remain in the Crown, and be disposed of by lease only under the Regulations to be effected by the Governor in Council;

(2) That title to water-power shall always remain in the Crown, rights to development and operation thereof being granted for limited periods only, subject to,

(a) The payment of rental for privileges enjoyed;

(b) The control of rate to consumers;

(c) The production of power to meet all public demands, and in a manner which will realize the maximum advantageous use of the resources; and

(d) The ultimate reversion of the development to the Crown, upon fair payment therefor, if at the end of the term of the concession it is considered desirable that the project be taken over by or for the general public.

(3) For expropriation by the Crown of properties necessary for power development purposes;

(4) For the extension of expropriation rights to those persons authorized to develop power under the regulations;

(5) For a comprehensive survey and investigation of the power resources of the Prairie Provinces.

Provisions for the details of administration is left largely to the Governor in Council. This is considered necessary because the principles governing these details have, owing to the rapid strides in the art and practice of hydraulic and electric engineering and to the complexity and almost indefinite ramifications of the interests involved, not yet been definitely and finally worked out in any previous jurisdiction. As is well-known, the administration of water-powers is interwoven with questions affecting public utility enterprises such as municipal lighting systems, electric railways, etc., and principles affecting these problems are still in a formative stage.

In other countries, particularly France and the United States, where the investigation, administration, and development of water-power has been given a great deal of close study by Government, it has been found very difficult to enact suitable water-power legislation, largely because attempt was made to provide in proposed legislation for too much detail. It is now recognized that the most satisfactory way to enact water-power legislation is to assert general principles only in enactments and permit therein considerable latitude for the elaboration of detail by the governmental administration. This Bill leaves the establishment of appropriate water-power regulations to the Governor in Council, who can, subject to the general principles of the Bill, amend the regulations from time to time as the accumulated experience of Government officers may recommend, in order to meet investigations in engineering practice and the expansion of the use of hydro-electric energy.

Importance of Legislation

As an indication of the importance of appropriate water-power legislation for the Prairie Provinces, it might be pointed out that there is over 4,365,000 horse-power available of development, made up as follows: Alberta, 471,000 h. p.; Saskatchewan, 576,000 h. p.; Manitoba, 3,218,000 h. p. These figures are of course, exclusive of the large power possibilities within the Northwest Territories. On the Winnipeg river alone in the province of Manitoba, departmental investigations show that there are nine power sites capable of development and affording an untimate total production, under regulation conditions, of nearly 500,000 h. p. Competent engineers state that their power situation on the Winnipeg river is unique and can probably not be duplicated anywhere on this continent. Having in mind that the power capacities of this river are sufficient to meet all the requirements of a population of 3,000,000 people, and that it is all within 75 miles of Winnipeg, it will be realized that adequate water-power legislation is a vital necessity, if this unique and unequalled situation is to be preserved and protected in the best interest of the public for this and later generations.

Another power situation of immediate importance, to which the legislation will apply, is that on the Bow river in the Province of Alberta, where at six power sites, all within 65 miles of the City of Calgary, it is possible to develop about 60,000 h.p.

In the provinces of Manitoba and Alberta there is at present invested, approximately, $15,000,000 directly in hydro-electric undertakings, and there is under contemplation in the immediate future hydro developments which will involve a capital expenditure of several additional millions.

Key To Industry

The war has shown beyond peradventure that cheap, dependable power is the key to all industry. Governments of every allied country have been giving special attention to the general problems of power production, with the primary object of determining definitely the various available sources of power, and to provide for their co-ordinated and concomitant development and use, in order that the power needs of the countries may be met in the most advantageous and economical manner.

Statistics show that Canada enjoys a position with regard to power, both developed and potential, second to no other country. Within economic transmission range of every commercial centre in the Dominion are sources of power capable of meeting all anticipated requirements of the future, and the truly remarkable feature of this fact is that, except in the central portions of the Prairie Provinces, where there is suitable natural gas and coal, the most economical and permanent source of power is water-power.

A census of power production in Canada, but recently completed by the Dominion Water-power Branch of the Department of the Interior, discloses the following exceedingly gratifying information: there is developed and in use in Canada to-day 2,300,000 h.p. generated from water. This is equivalent to a development of 276 h.p. per 1,000 population. Norway and possibly Sweden are the only countries where the per capita utilization of water-power exceeds that of Canada.

Of the total power developed, 1,725,000 h.p. is generated in hydro-electric central stations for sale, while some 350,000 water horse-power is utilized directly in the pulp and paper industry in adition to 100,000 hydro electric power purchased from the central stations.

In the central station industry alone —that is to say, the industry having to do with the development of electrical energy for sale—90 per cent. of the power is derived from water. This percentage is extraordinarily high, and is indicative of the extent and availability of the water-power resources of the

Dominion and of the remarkable degree in which their adaptability for central electric station work has been appreciated in principle and realized in practice. The Yukon develops 97.4 per cent. of its primary central station energy from water. Ontario develops 95.7 per cent.; Manitoba, 95.2 per cent.; Quebec, 94.9 per cent.; and British Columbia, 89.8 per cent. These high percentages result from the fortunate location of our hydro-electric resources close to the centres of population, industry, and commerce throughout the Dominion.

Huge Sums Invested

In the hydro central stations throughout the Dominion there is directly invested to-day $285,000,000. This does not take into consideration the vast amount of capital invested in interests which are dependent for their maintenance and operation upon power secured from the central stations, nor does it include the capital invested in water-power plants other than central electric stations. The figures are, however, indicative of the vast dependence which the Dominion has already come to place upon its water-power resources and is an assurance of what the future holds in store.

If the remarkable expansion in the development and use of our water-power resources is to be projected in the future, there must be adequate legislation and administration. The Dominion Water-power Bill is intended to furnish this used in so far as the provinces of Manitoba, Saskatchewan and Alberta, and the Northwest Territories are concerned.

EXTERNAL CORROSION OF BOILER

A unique case of external uniform corrosion occurred to a coke-fired Galloway boiler which supplied steam to gas works. There was not the least indication of moisture in the flues or of corrosion due to dampness, and the inside of the boiler was in an apparently perfect condition, but while the inspector was sounding the shell plate with a hammer his suspicion was aroused with regard to the side plates at the back end of the boiler, and after a careful re-examination it was decided to drill the shell plates just below the side flue covering. Originally these plates had been 7-16 in. thick, but it was now found that they had been reduced to 3-32 in. at the back end, and to about 5-16 in. at the forward end, but only for a width of about one foot below the side flue coverings. Under the brickwork there was practically no corrosion. It was also noticed that the outside of the shell plates was covered with a pale-reddish scale, which on examination was found to consist of dehydrated sulphate of iron (green vitriol or copperas) and red oxide of iron. Our chemist then examined the boiler and found that this sulphate scale extended from just beyond the bridge all over the heating surface of the boiler except where it was protected by flue dust and ashes. It was thickest at the upper portion of the side flues. The only previous case of this form of wasting of which we had any knowledge was reported in 1888 as having occurred at some Belgian works, but the reported details were too few to be of any practical use. It was at first thought that the coke with which these boilers were fired had been slaked with water containing sulphate of ammonia, but it was definitely established that town's water had always been used. Except, therefore, that these boilers were fired with coke, their treatment was the same as that of any other boiler.

A careful enquiry was then made into the question of the production of sulphuric acid and its power of corroding iron. It can hardly be said that it solved the mystery, but its results may prove of future use, and will be briefly recorded.

When coke or coal is burnt, the sulphur contained in these fuels is converted into sulphur dioxide (SO_2) known as sulphurous acid or anhydride, which has the well-known smell of burnt sulphur, and this is generally associated with traces of sulphur trioxide (SO_3), also known as sulphuric anhydride, a gas which escapes from fuming sulphuric acid. Dry sulphur dioxide (SO_2) will not attack steel or iron unless heated to near redness, which heating could not possibly have taken place in the flues of the boiler under consideration. We have, however, had a few serious cases of wasting by SO_3, due to the use of mechanical stokers, an intensely hot flame and local accumulations of scale close to the furnace flanges. These parts of the furnace must have become overheated and were attacked by the sulphur dioxide to such an extent that they finally wore through and leaked. The conditions in the side flues of the present boiler were such that this action could not possibly have taken place, and attention was therefore centred on the sulphur trioxide.

This gas can be produced from sulphur dioxide by mixing it with air and passing the mixture over a catalytic agent, the most common one being moist nitric acid in the lead chambers of sulphuric acid works, or platinum sponge, but red oxide of iron was found to be an almost equally efficient catalytic agent, for by merely dusting the inside of a glass tube with rouge (red oxide) and heating it, a mixture of the dioxide and air was readily converted into trioxide. Seeing that some makers paint their boilers with red oxide before sending them out, it is possible this oxide might effect the conversion, but it is difficult to explain why thousands of other boilers which were also painted red did not suffer like the present one.

Sulphur trioxide like the dioxide will not attack cold iron, and it is doubtful whether it will attack it when heated. On the other hand, when the trioxide is mixed with water, the mixture is known as sulphuric acid (oil of vitriol) which will attack iron very energetically if it contains an excess of water. After a careful study of the vapor tension of this acid the conclusion was arrived at that the corrosion in this boiler had not been active while the boiler was in use, but that sulphur trioxide or perhaps sulphuric acid had been absorbed by the scale on the boiler plates, and then when the boiler was lying idle and was cold, moisture from the atmosphere had been absorbed by the very hygroscopic calcined green vitriol until a fairly dilute sulphuric acid had been formed. This would be prevented from trickling down the sides of the boiler plates, because, being in contact with them, it would attack them and form more green vitriol crystals which would remain in place. The suggestion therefore is that the elements of sulphuric acid were formed while the boiler was at work, but that the actual corrosion only took place when the boiler was idle.

As already mentioned, cases like the above seem to be extremely rare, but possibly, now that attention has been drawn to this one, similar ones will receive special attention, and a careful watch should be kept on boilers which are burning coke. If similar cases should be discovered and the corrosion checked in time, the space devoted to this one will not have been wasted.—C. E. Stromeyer in Memorandum to Manchester Steam Users' Association.

It is not generally known that sea lions played a most important part in sea warfare. The British Admiralty used these animals to hunt U boats. First the animal is trained to follow sounds from the water's depth. After graduation it is put overboard whenever U boats are believed to be in the vicinity of the ship. These animals proved a decided success and well worth the trouble spent in training.

Now comes the long-spouted oil can for lubricating revolving shafting, without going up to the danger zone. You merely stand on the floor, place this special oil can in position, press a button and out comes the oil. The inventor if this new can claims that dozens if not hundreds of lives will be saved with his device.

* * *

Salonika will become one of the most important ports of the near East if improvements started by the Greek Government are carried out. Expenditures of $100,000,000 are planned, and include a city water supply, drainage and sewer works, dock extensions, railway stations and underground railways, 100 miles of new streets with housing developments, theatres, etc.

* * *

If equal parts of copper and antimony are melted together it forms an alloy of a beautiful violet color, which takes a nice polish, but, being too hard for many purposes, a substitute can be produced by taking an iron casting and copper plating it, after which immerse it for a moment in a solution containing antimony.

What the Mechanical Soot Blower Accomplishes

The Following Article Gives Results of Actual Detailed Tests of Mechanical Soot Blowers in a Modern Power Station—The Importance of Keeping Tubes Free From Soot is Emphasized

By ROBERT JUNE, Mechanical Engineer

THE economies effected by the use of mechanical soot blowers, due to reduction in quantity of coal required, increased boiler efficiency and increased steaming capacity, have been generally recognized by engineers in recent years. Owing to inherent difficulites, however, there have been very few detailed tests made. As those here recorded are in the opinion of the present writer the most accurately carried out, and the most complete ever made, it is believed that they will prove of considreable interest to engineers everywhere.

During the past winter one of the big American railways, the name of which cannot at present be disclosed without breach of confidence to certain of its engineers, decided that the cost of producing power at one of its large shops was excessive and that the possibilities of effecting a reduction through the medium of mechanical soot blowers should be thoroughly investigated.

Power is supplied to the shops from two plants, designated as East Boiler-room and West Boiler-room. The equipment in the first consists of 14 B. & W. boilers of 520 h.p., and in the second of 14 Bigelow-Hornsby of 625 h.p. One boiler of each type was selected and Diamond soot blowers chosen for the purposes of the test.

Boiler Equipment

The B. & W. boiler known as No. 530 is one of the inclined header type, having three longitudinal drums, 252 four-inch tubes and equipped with the B & W. superheater. The total heating surface, including superheater, is 5,734 sq. ft. and manufacturer's rating is 520 b.h.p. Steam pressure is 196 lbs. gauge and safety valve blows at 200 lbs. See diagrammatic sketch of this boiler, Fig. 1.

Boiler No. 530 has under it a Roney mechanical stoker, as have all the B. & W. boilers. This stoker is of the overfeed type, with inclined grate, having an area of 94½ sq. ft. The stoker is operated by means of a small Westinghouse engine. Induced draft only is furnished by four fans under the stack, which can be grouped by means of dampers in various combinations. The fans are regulated by Mason regulators of the usual balanced pressure type. The boiler was equipped with a standard five element mechanical soot blower, as shown on the sketch.

Bigelow-Hornsby boiler No. 544 in the West boiler-room was the one selected for the trial on this side of the plant, consists of ten groups or units of inclined tubes in the front over the furnace, and ten groups of vertical tubes in the back of these with vertical type Foster superheater in between. Each group or unit of tubes contains twenty-one 3¾ inch steel tubes, so that there is a total of 420 tubes in the boiler. All tubes fit into so-called unit drums. In each of these the ten top drums are connected to the main cross drum. The total heating surface of boiler is 7,322 sq. ft. Manufacturer's rating is 625 b.h.p. steam pressure and safety valve setting are similar to that on the B. & W. boilers. See Fig. 2.

The stoker under this boiler is of the Taylor seven retort, underfeed type, having a grate area of 105 sq. ft, inclined grate. Forced draft was supplied to this stoker by 1x3 Sturtevant turbine-driven multivane double inlet fans, under control fans by means of roller chain, but in this test the forced draft and stoker drive was separated and stoker was driven by one of the Westinghouse engines recently installed on the boiler room floor for the driving of stokers. Induced draft was obtained by means of fans located at the uptake to the stack.

The soot-blowing equipment on this boiler consists of six elements versus five on the B. & W. boiler and are located as shown in the sketch. The perforations in the elements A, C, D, and F are arranged in five groups of four holes each on the opposite side of the pipe, and five groups of two holes each on the opposite side of the pipe. The elements are set so that the issuing streams of live steam will play in along the tubes. Element B has a set of evenly spaced holes on one side only, similar to the B. & W. elements. This is essentially a baffle blowing element and the stop with which it is equipped prevents the hand wheel from being turned to a position where the jet will play directly on to the baffle to the detriment of the latter. Superheated steam is used on this boiler, the supply being taken from the point in the boiler outlet just before the main valve. In other respects the installation is similar to that of boiler No. 530.

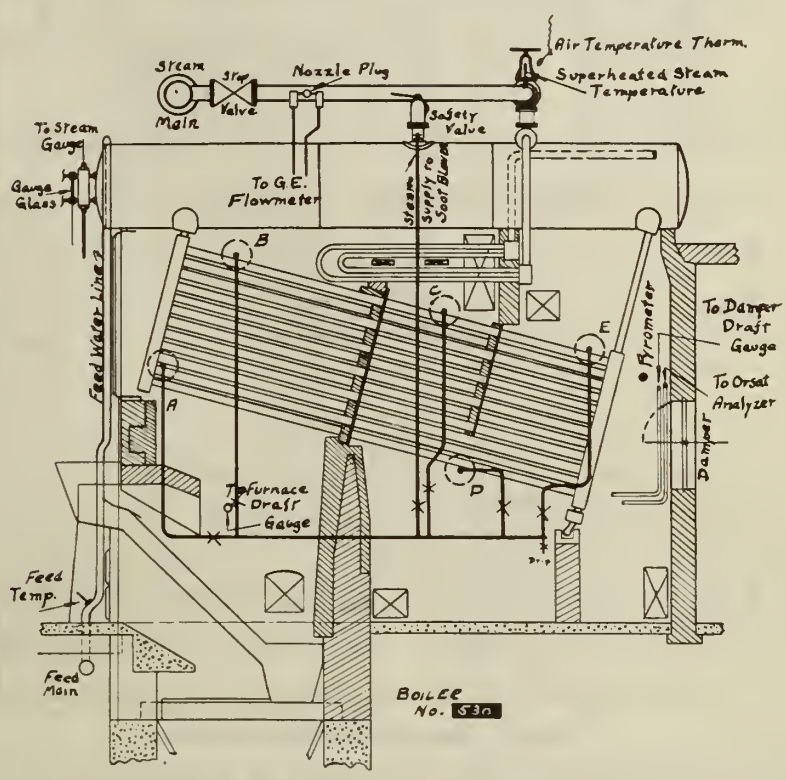
SOOT BLOWER INSTALLATION SIMILAR TO THAT IN WHICH TEST WAS MADE.

Instrument Equipment

On boiler No. 530 the steam output was obtained by means of a General

Electric flow meter, recording, and integrating type, with nozzle plug installed at the boiler steam loop on the roof of the boiler. Consumption of coal was obtained by means of the traveling weight hoppers used in the regular service, each filling of the boiler hopper being obtained by weighing and indicating on the card the weight of larry before and after filling the boiler hopper. Superheated steam temperature by means of an indicating mercury thermometer placed in the steam loop near the boiler stop valve, and a similar range thermometer for obtaining the steam temperature was suspended from the valve hand wheel. Steam pressure in the drum was obtained from the steam gauge used in the regular service on the boiler front. The temperature of the boiler feed water was obtained by means of an indicating mercury thermometer placed in the 2½ inch feed line about one foot from the boiler-room floor. The uptake of the flue gas temperature was obtained by means of a six foot Thermo electric pyrometer inserted through a hole in the side of the boiler wall and arranged to extend across the damper. A mercury thermometer was suspended on the boiler wall to obtain cold junction temperature. For obtaining carbon dioxide in the flue gas a ¼ inch pipe was run through the boiler wall, across the breechine, with a horizontal extension containing a number of evenly spaced perforations. This pipe was brought out and led to the compressed air inspirator and a small portable gas analyzer. Draft at the damper, over the grate, and in the furnace was obtained on a two pen recording draft meter. No indicated readings were obtained. All of the above, together with the regular water gauge glass on the boiler front, constitute the testing outfit on this boiler.

On boiler No. 544 steam flow was obtained by means of two meters, one an integrating recording indicating General Electric meter, already installed and used in previous tests, the other a newly installed Bailey boiler meter. Weight of coal was obtained from the traveling weight hoppers and larry tickets, as in the case of boiler No. 530. A revolution counter was placed on the Taylor stoker to count the revolutions of the main power shaft. The thermometer for obtaining superheated steam temperature and that for obtaining feed water temperature were placed in thermometer wells in their respective pipes at the top of the boiler as in previous tests. The uptake temperature was obtained from three pyrometers inserted into the flue above the damper and inserted at 4, 5 and 6 feet respectively. The cold junction temperature was obtained by means of an indicating thermometer suspended over the cold junction of the pyrometers. Steam pressure was obtained from the steam gauge in regular service on the drum. A steam correction thermometer for obtaining the superheated steam temperature corrected. The carbon dioxide of flue gas was obtained by means of a sampling tube already installed and used in previous tests in conjunction with a standard Orsat gas analyzer. Draft over the furnace and at the damper was obtained on the indicated gauge. Pressure in the wind box was indicated on the lower gauge and on the recording pressure gauge. In addition to the above, the Bailey meter indicated the draft over the furnace and the air flow through the boiler. The latter being obtained by means of two 1½-2 inch pipe connections, one to the combustion chamber over the furnace, and the other in front of the damper at the same height as the first. The various items indicated above, and constituting the testing apparatus on this boiler, are shown in the accompanying sketch.

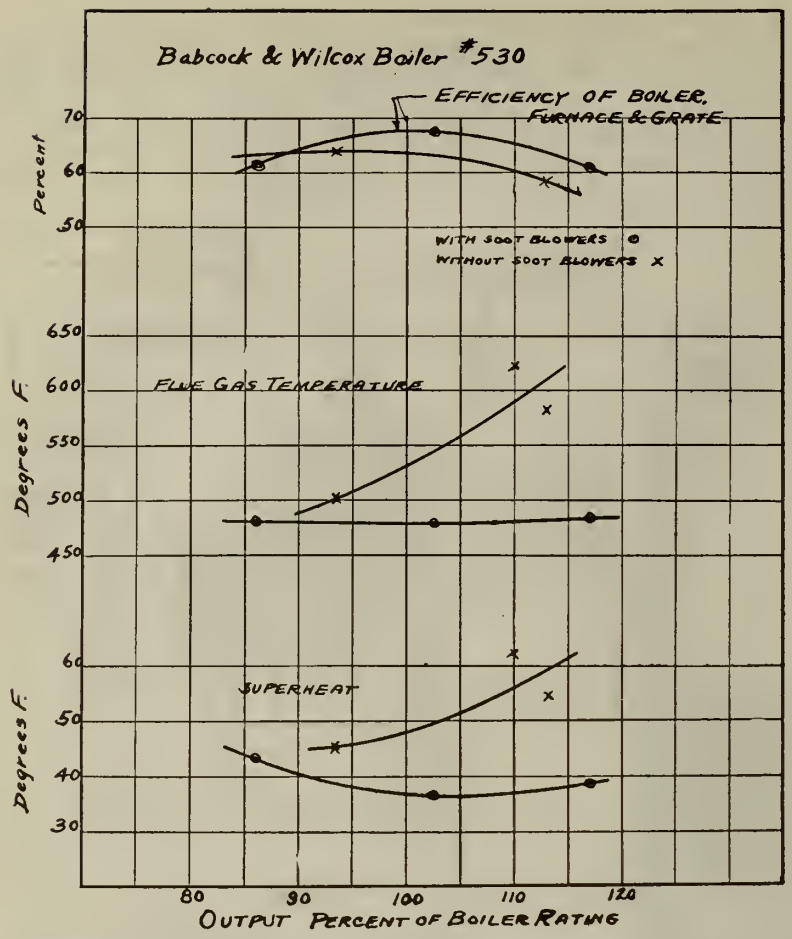


BABCOCK AND WILCOX BOILER WITH B. AND W. SUPERHEATER, SHOWING ARRANGEMENT OF SOOT BLOWING ELEMENTS AND LOCATION OF INSTRUMENTS AND CONNECTIONS FOR TEST PURPOSES.

Method of Test

1. Boiler No. 540 was taken out of service November 15, 1918, for cleaning and installation of the new soot blowers. The boiler was thoroughly cleaned inside and out, and after the new soot blowers were installed the boiler was cut in on the line Feb. 3rd, 1919, at 6.00 a.m. Between this time and Feb. 6th, the setting was allowed to warm up thoroughly, and the new soot blowers were operated three times a day to keep the heating surface clean. The test began on Feb. 6th at 9.30 a.m. The method was to run a series of tests without the soot blowers, attempting to grade the runs from 75 per cent. load to about 200 per cent. load, each run to extend for 24 hours. This was to be followed immediately by series operating the soot blowers, duplicating the loads and conditions of the first series as closely as possible. This boiler was operated mainly by the regular boiler-room operating crew, requiring little supervision by the man in charge of the test. The hopper was filled promptly at the beginning of the test. The fire was cleaned whenever necessary by the fire-room crew.

Readings were taken every twenty minutes by the tester of the following quantities: Steam flow, steam temperature, steam pressure, temperature of the feed water, flue gas temperature, draft in the furnace, and at the damper; the level of the water in the gauge glass, and an analysis of the flue gas for carbon dioxide only, this being sufficient for the purposes, and lack of time not permitting a complete analysis of the gas. The fire room crew were guided by the steam flow meter in maintaining the load, and also by regulating the opening at the dampers on other boilers. During the test, with soot blowers, the latter were operated every six hours. The operation consisted of turning on the steam in the supply header, then in turn turning on the steam in each element and by means of the chain around the hand wheel turning the element three times in both directions as far as possible. This operation for the entire boiler occupied between ten and fifteen minutes. At the completion of each run the fire was burned down and cleaned before the next run was started. When attempting to make Run 4 on this boiler, at about 200 rating, it was found not possible on account of the combination of the following reasons: The coal was very poor; draft at the damper was not available for all the boilers, which were in line, and it developed that the boiler setting leaked quite badly at the front doors.



GRAPHICAL SUMMARY OF RESULTS OBTAINED IN PERFORMANCE TEST OF SOOT BLOWERS, BOILER NO. 530.

Therefore, only six runs were made on this boiler, three with and three without the soot blowers. During the runs without operating the soot blowers the boiler was not cleaned at all, since in regular service the frequency of cleaning by the hand lance is only about once every four or five days. In this way actual operating conditions were reproduced as nearly as possible. The test may be called, in fact, a test of the boiler for its operating capabilities.

Boiler No. 544 was cut out of service November 22nd, 1918, for thorough cleaning and installation of the new soot blowers. After this was completed the boiler was cut in on the line at 5.00 a.m. Feb. 3rd, 1918. Boiler setting was allowed to warm up thoroughly and soot blower was operated both to familiarize the operator with the instrument and keep the heating surface perfectly clean. The actual test was started Thursday, Feb. 6th, at 9.00 a.m. On this boiler the fire-room crew did not take such particular pains to maintain the load as in the case of No. 530. The fire-room crew worked in conjunction and under the supervision of the man in charge of the test. Load was maintained by means of observations of the steam flow and the air flow pens on the new Bailey meter, regulating the damper opening, wind box pressure, and other boilers on the line in order to do this. The duration of each run was 24 hours as on No. 530. At the beginning of each run the fire was cleaned and the hopper filled. The tail grate was cleaned whenever found necessary by observation of the fire. This varied from about every two to four hours, depending on the load. The operation of the soot blowers was exactly similar to that on No. 530.

On this boiler eight runs in all were made, the first four being with soot blowers and the second four being without the soot blowers, attempting to reproduce the conditions of the first four as nearly as possible. In doing this, the fire-room crew and the tester were guided by the average conditions attained in the first four runs. Readings were taken every 20 minutes, starting on the hour and ten minutes before readings were taken on No. 530. In the case of this boiler, as also in the case of No. 530, the steam utilized by the soot blowers was not registered by the steam flow meters, owing to the fact that the meter connections to the boiler are placed at a point which is not passed by the steam used in the soot blowers. In boiler No. 544 the steam was used along the inside walls and bridgewall to decrease the accumulation and adhesion of clinker. This is a connection in operation during regular operation and was left so during the test; this steam also was not taken into account by the steam flow meter. Readings taken were as follows: Steam flow, air flow, and furnace draft by gauge, wind box pressure, the speed of the stoker line shaft, the

(x) Test 1 started Feb. 6th at 9 A.M. Each succeeding test started one hour later in the day than the preceding one.

number of revolutions of the stoker power shaft, steam temperature, feed water temperature, flue gas temperature, on three pyrometers, cold junction temperature, air temperature, steam pressure and carbon dioxide in the flue gas.

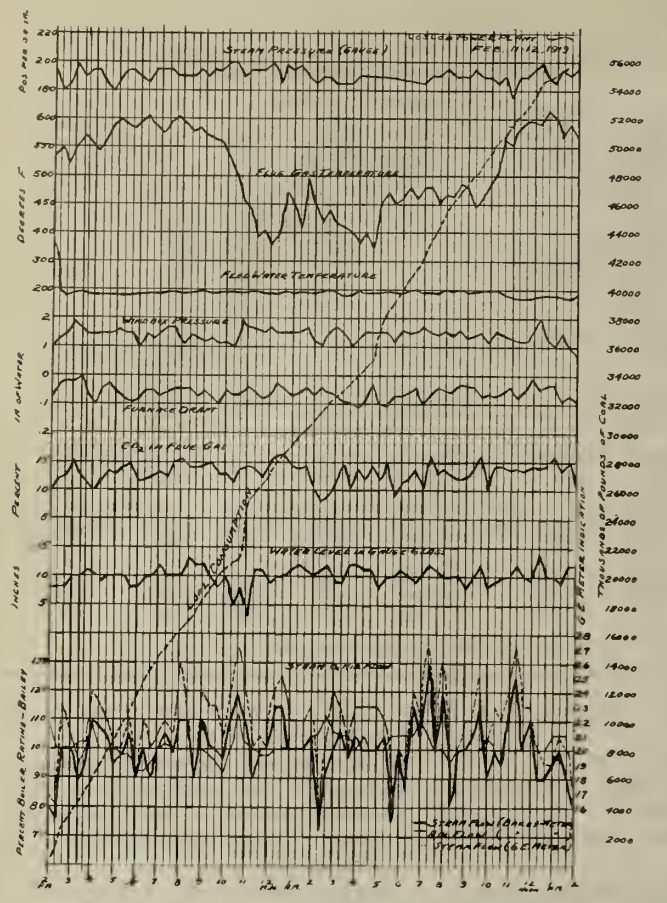
Forced draft was obtained from No. 3 blower, which was isolated from the other blowers by closing the division damper. It was kept running throughout the entire test and the draft to the boiler was regulated by means of the control at the boiler. Since the stoker drive was independent of the blower, being driven by No. 5 stoker engine on the boiler-room floor, the rate of coal feed was varied at will to suit the needs of the load.

Sample Calculations

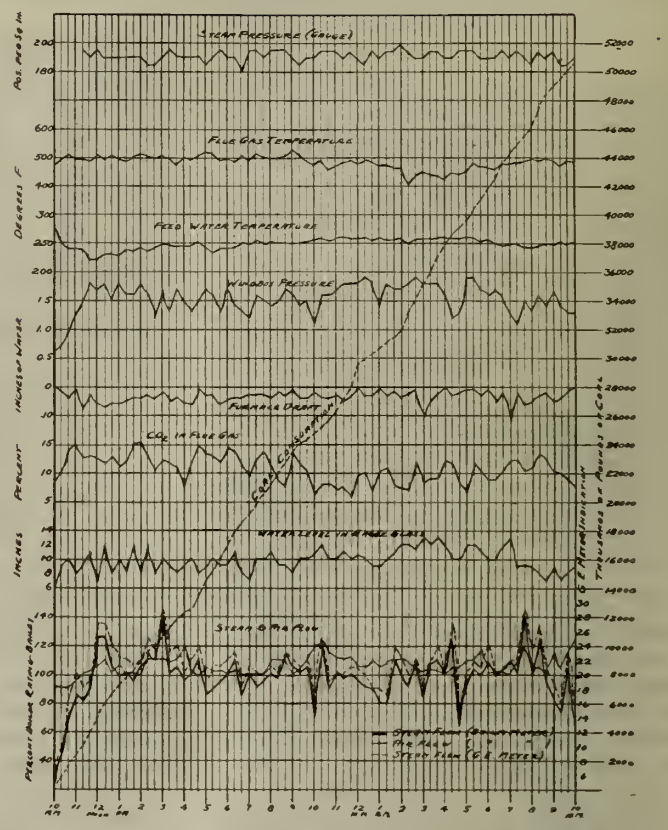
The following are the calculations for arriving at the results of Run 4 on boiler No. 544, which extend from Sunday, Feb. 9th, at noon to noon Monday, February 10th, 1919.

The numeral in parenthesis following each item corresponds to the items having similar numbers in the tabulated results:

1. Average steam pressure, lbs. per sq. in. gauge (drum).
   Average of 73 readings on log sheet, 193 (3).
   Absolute pressure: 193+14.7=207.7 lbs.
2. Average temperature of feed water °F.
   Average of 73 readings on log sheet —179 (4).
3. Average superheated steam temperature.
   Observed temperature average of 73 readings: 476°F.
   Steam correction: .000085 x (476—250) 476—107) = 7.1°F.
4. Average superheat, °F.
   Temperature in Drum corresponding to 207.7 lbs. absolute pressure—385.1° F (from steam tables).
   Average superheat: 483.1 = 98°F (6).
5. Uptake gas temperature °F.
   Highest of three averages for three separate pyrometers
   Observed temperature average 73 readings—522°F.
   Correction for cold conjunction temperatures (Calibrated at 75°F.) 101—75 = 522 plus 26 = 548 (7).
6. Average CO^2 (per cent.).
   Average of 73 readings from log sheet —11.6° (8).
7. Proximate analysis of coal:
   Moisture .... 0.65 %—9
   Volatile .... 22.05 %
   Mixed carbon ..... 65.95 %
   Ash .... 2.12 %
   B.t.u. 13,572
8. Total coal as fired, pounds:
   From larry tickets, 102,515 (10).
9. Total dry coal fired, pounds.
   Moisture in coal—102,515 x .0065 = 666 lbs.
   Total dry coal = 102,515—666 = = 101, 849 (11).
10. Dry coal per hour, pounds:
    Item 9 / 24 = 4,243.7 lbs. (12)
11. Dry coal per sq. ft. of grate area per hour:
    Area of grate: 105 sq. ft.
    Item 10 / 105 = 40.4 (13)
12. Total actual evaporation:
    A .By Bailey boiler meter:
    Steam pressure at orifice gasket (assuming three pounds drop-through superheater)—190 lbs. gauge. Average reading of steam flow pen for 24 hrs. (See photostat of Bailey meter chart)—174.4%.
    Actual weight of steam per hour for 190 lbs. and 98° superheat (corrections according to Bailey meter instructions).
    1.744 x 20,200 x .990 x 995 = 34,-703 lbs. hr.
    B. By General Electric flowmeter:
    Average pen reading from flowmeter chart—6.8. Multiplying constant: (From manufacturer's instructions):
    6900 x .829 x 1.115 x 1.0 x 717 = 5119.1.
    Actual weight of steam per hour, 5119.1 x 6.8 = 34,810 lbs. average.
    Average of Bailey and General Electric—34,756 lbs. per hr.
    Total steam output for 24 hours as meter: 34,756 x 24 = 834,144 (14).
13. Factor of Evaporation:
    (From steam tables)—1.444 (15).
14. Total equivalent evaporation from and at 212°F. pounds. Item 12 x Item 13 = 954,261 (16).
15. Equivalent evaporation per hr. from and at 212°F.
    Item 14 / 6250 = 39,761 pounds (17).
16. Equivalent evaporation per hr. from and at 212°F. per sy. ft. of heating surface:
    Item 15 / 6250 = 6.25 (18).
17. Rated capacity per hour from and at 212°F.:
    625 B.h.p. x 34.5 = 21,563 (19).
18. Percentage of rated capacity developed:
    Item 15 / Item 17 = 184.6% (20).
19. Equivalent evaporation from and at 212°F. per lb. of dry coal:
    Item 15 / Item 10 = 9.38 (21).
20. Heating value of 1 lb. of dry coal: 13,572 B.t.u. (from item 7) (22).
21. Efficiency of boiler, furnace and grate:



GRAPHICAL LOG, SOOT BLOWER TEST, BOILER NO. 544, RUN VI., TUESDAY, FEB. 11, 2 P.M., TO WEDNESDAY, FEB. 12, 2 P.M.



GRAPHICAL LOG, SOOT BLOWER TEST, BOILER NO. 544, RUN II., FRIDAY, FEB. 7, 10 A.M., TO SATURDAY, FEB. 8, 10 A.M.

Item 19 x 970.4
——————— = 67.1% (23).
Item 20

Calculation of Composite Results for Runs 1 to 4 on Boiler No. 544 With Soot Blower

1. Average uptake gas temperature.
   Final corrected uptake temperature for each run added together and averaged, 499.6°F.
2. Total dry coal.
   Total dry coal for each run added together, 260,587 lbs.
3. Total equivalent evaporation from and at 212°F.
   Sum of equivalent evaporation for each run added, 2,591,638.
4. Rated capacity from and at 212°F. lbs.
   96 hours (for 4 runs) x 21,563 = 2,070,048 lbs.
5. Per cent. rated capacity developed:
   Item 3
   ——— = 125.2%.
   Item 4.
6. Equivalent evaporation from and at 212°F. per lb. of dry coal:
   Item 3
   ——— = 9.96 lbs.
   Item 2.
7. Heating value of 1 lb. of dry coal.

This was determined by weighing the calorific value for each run according to the proportion of the total coal consumed during that run, as follows:

1	2	3	4
	Dry Coal consumed per run, lbs.	B.T.U. of 1-lb. Dry Coal.	Per. Cent. of Total Dry Coal Consumed. (1 divided by total)	Portion of B.T.U. Assigned to composite 2 x 3
Run 1	35,713	13,827	13.7%	1,890 B.T.U.
Run 2	50,190	14,042	19.2%	2,700 B.T.U.
Run 3	72,835	14,223	28.0%	3,970 B.T.U.
Run 4	101,849	13,572	39.1%	5,280 B.T.U.
		Composite Heating Value		13,840 B.T.U.

8. Efficiency of boiler, furnace and grate:
   Item 6 x 970.4
   ——————— = 69.8%.
   Item 7

A summary of the principal data and results of the test on boiler No. 544 is given herewith as Table 1. The same material has been tabulated for boiler 530, but as it does not materially differ, it is not here included.

Referring to boiler No. 544, it will be seen that the ratings attained in the run with soot blowers varied from 71.6% to 184.3%, or normal, with an average of 125.2% for the four runs. The ratings without soot blowers varied from 76.3% to 168.2%, with an average of 120.3%. This again indicates a fairly close duplication in the second series of conditions in the first series. It may not be out of place to say here that although it was attempted to hold certain definite average conditions in the first series, and this was not as successful as could be desired, yet the second series was a duplication of the first as nearly as possible, because the entire test was to be comparative one between two methods of boiler operation under similar conditions.

Item No. 23 on the summary sheet for this boiler shows an average combined efficiency of 69.8% with soot blowers in operation, as against 68.4% without the soot blowers. This is an actual gain of 1.4%, due to soot blowers.

The average value of the flue gas temperature for the series with soot blowers, 499.6 deg. F., against 535.7 deg. F. without the soot blowers. This represents a decrease of 36.1 deg. using soot blowers, as in the case of boiler No. 530, means that with the soot blowers in operation, the boiler has absorbed more heat from the gases, due to cleaner heating surface, than without the soot blowers. The effect on superheat, as indicated in the graphical summary, was about the same as for boiler No. 530, but not so marked.

It has been stated previously that with the present practice of cleaning the boilers with the hand lance, each boiler is cleaned every four or five days. In the tests on boilers No. 530 and No. 544, without soot blowers, in order to reproduce this condition, the series was started with the boiler heating surface clean and then left without any cleaning during the series. If the series had been

extended for, say, an equal period, or longer, and if during that time the regular hand method had been used to clean the boilers on the regular schedule, it is very probable that a still greater rise in flue gas temperature and still greater decrease in combined efficiency would have resulted. This statement is made because it is believed that with the present hand method, owing to the fact that all soot is not removed, there is a gradual accumulation on the heating surface, the longer the boiler remains in service. Therefore, based on the above, it is safe to say that the results obtained were conservative, that a more exact test along the line indicated would show better results.

In addition to the above, may be mentioned the fact that operation of the soot blowers does not require the banking or shutting down of the boiler, while in order to remove the soot by hand method it is necessary to shut down the boiler for two or three hours, during which time the boiler setting cools and must be warmed up again. Here is a loss which is eliminated by the use of soot blowers.

It has been stated that the steam used by the soot blowers was not included in computing boiler efficiency. In other words, the boiler was charged with this steam. On the other hand, since no steam was used in the tests without soot blowers, the boiler was not charged with steam for this purpose, but it is equivalent that in a long series, as in actual practice, considerable steam would be used for cleaning by hand lance, which would have to be charged to the boiler, therefore further decreasing the combined efficiency.

In conclusion it should be noted that these tests were conducted in a manner calculated to indicate a minimum, rather than a maximum improvement by the use of soot blowers. It would have been fairer, in the writer's opinion (he was not connected in any way with the making of the tests) to have refrained from using the soot blowers at all before making the tests without soot blowers, using the hand lance only to clean the boilers at the regular periods of cleaning. Had this been done, the boilers would not have had the advantage of being thoroughly cleaned by the mechanical blowers when they entered the hand-hose test.

Table II contains a summary of the benefits, exclusive of decreased labor and labor turn-over, of using the soot blowers. It shows that even under the conditions given, the soot blowers would pay for themselves in a comparatively short time.

August 25th of this year is the centenary of the close of James Watt's life. At a meeting of the engineers of Birmingham (the city of his adoption) it has been decided to erect a James Watt Memorial Building to serve as a museum, and also to endow a professorship of engineering, to be known as the James Watt chair, at the University of Birmingham, for the promotion of research in the fundamental principles underlying the production of power and the study of the conservation of the natural sources of energy.

TABLE II.

Comparison of Composite Results With and Without Diamond Soot Blowers.

	Boiler 530	Boiler 544
Decrease in average uptake temperature with Soot Blowers	88%	36.1%
Percentage gain in efficiency of boiler, furnace and grate with Soot Blowers	2.15%	2.05%
Value of saving of coal per year based on 1918 consumption and prices—		
In West Boiler Room		$8,559.86
In East Boiler Room		5,503.19
Total saving		$14,063.05

Perpetual Motion

EVERY so often someone who should know better, someone with engineering experience and training, brings forth some perpetual motion scheme, usually in its conception as old as the hills. Sometimes it is an electrically-heated boiler, steam engine and generator and sometimes a generator and motor, variations being rung in by juggling the speeds of the machines or having them different. Most of these false conceptions as to the availability of energy arise through the confusion of speed of rotation with work.

Perpetual motion, as envisioned by its devotees, is distinct from the engineering principles often forming the basis of somewhat chimerical schemes for the utilization of the power inherent in wave motion or, as suggested by a correspondent writing to an American scientific paper, the utilization of the residual energy of tap water before it enters the sewer. Such things have as their basis some germ of engineering fact but fail through their application to things of little account.

Such is not the case with perpetual motion and anyone who has an idea, in its essence more foolish than the search for the philosopher's stone, transmuting base metals into gold, would be well advised to hie himself to a secluded corner and apply the principle of the conservation of energy to his own thoughts and to their misguided conceptions.

The nearest approach to a source of inexhaustible energy obtained without effort is found in the action of the radio-active elements, and in this case, enormous as is the store of in intra-atomic energy and lengthy as is its life, it is not everlasting but slowly diminishes and is created at the expense of the radio-active element itself, the final product being lead of a slightly varying atomic weight.

Using Power of the Tides

THE feasibility of securing a supply of electrical energy from the tidal waters in the coastal rivers of Britain is again being made the subject of close study. For some time this question has been approached more as an academic perennial than as a practical accomplishment.

Judging from figures that are now out there has been a real move made. J. Smith & Co., engineers of Glasgow, have worked on the idea for years, and are well posted on all needful data. The river Severn at Pitshead, for instance, supplies (on paper as yet) 4,773,730 H.P. The Dee, in North Wales, at Point of Air, Manai Straits, and the river Mersey above Liverpool Docks—show a total of 5,651,984 H.P. It is claimed that by this scheme power could be generated and sold at a fraction of the present prices.

An explanatory guide to the tidal waters power scheme has been prepared by Mr. Smith, who points out that on all rising tides the head water runs through turbines into inside of weir; on all ebbing tides the water runs through turbines to outside of weir. All doors are closed at low water, keeping out the rising tide; also at high water, keeping in full tidal water. All rivers start turbines working at half tide rising or falling. This gives the half tide head for the working of the later half. There being about three hours between the time of high water at the weiring point in the Severn and the other rivers, this gives three hours' run for the Severn, starting at half rising tide—say, 17 ft. head—inside water being at low water and finishing at high water, 34 ft. minimum tide. The other rivers being now at half rising tide, they take over the working from the Severn until high water on their rivers.

The scheme has in view the furnishing not only of power, but of light to all the homes in Britain.

It's The Net That Counts

MR. DOOLEY was one of the leading restaurant keepers in a small town. Recently he purchased a cash register. The documents of the first trade to be recorded were a 27-cent check and a five dollar bill, the proud proprietor rang up $5.00 and paid out $4.73 in change. When the next customer presented his check it was for 35 cents and a $10 bill was passed over the counter. Dooley operated on the $10 key. Thus things progressed throughout the day. That night, upon checking up, he discovered according to the machine that he ought to have $250.00 on hand, although a careful inventory revealed only $17.30.

"Terrance," said Dooley to his assistant, "have yez taken anything out in the new cash machine to-day?"

"Shure," said Terrance, "I took me carfare home."

"And where d'yez live," inquired Dooley, "Australia?"

Like Mr. Dooley, many a man in charge of a business is ringing up gross profits without the faintest idea of what his net profits really are. And like Mr. Dooley, if he keeps on hammering the gross receipt button, he is "going to have a disappointment in his life," as the fortune tellers say, for after all it's getting the net that counts.

Mr. Wills Maclachlan was elected one of the vice-presidents of the American Institute of Electrical Engineers at the annual meeting of the Institute held in New York, May 16.

* * *

Mr. F. T. Kaelin has been appointed chief engineer of the Shawinigan Water & Power Co. He was formerly assistant chief engineer, and joined the staff in 1902, coming to Canada from Switzerland.

* * *

In considering belt efficiency, grip and tension are terms often confused. Increase of tension certainly gives a firmer grip, but additional strain is thereby thrown on the driving shafts. An increase of grip due to suitable dressing is free from that disadvantage.

* * *

SOME wise men have it all figured out that people should produce more and save more. With the first suggestion no person is going to find fault, but with the latter there is good reason to start an argument. Will some of the wiseacres please go into detail and show how anything can be saved while everything necessary to existence camps on a peak-load basis?

* * *

A French patent has been granted to P. L. Weston, for the use of thin steel or iron belts on magnetized pulleys for the transmission of power. The magnetization of the pulleys is effected by windings lying in helicoidal slots on the surface of the pulleys. The thickness of the belt should not exceed about 0.06 times the diameter of the smallest pulley.

* * *

With a steel belt of 1-6 in. thickness making contact over an arc of 145° on a pulley of 10 in. diameter running at 4,000 R.P.M., it is possible to transmit more than 200 H.P. per inch width of belt. With a pulley of 50 in. diameter running at 800 R.P.M., a belt of 1 in. width will transmit 1,000 H.P. Steel belts may be run at speeds of 18,000 ft. per minute, so that this method is suitable for speed reduction with turbines.

* * *

The use of electricity in industry saves both fuel and labor. This fact is recognized throughout the world to-day and in order to secure these advantages practically all the nations are now considering plans for the electric generation of power. In England, Belgium and France, among others these plans are being prepared by official commissions, so that a tremendous activity in electrical power development may be expected following the advent of peace. In all cases the ideal in view is a broad one to use electricity for all possible power purposes, including railway operation.

* * *

The science of measuring has developed to such an extent for industrial purposes, in connection with gauge making, that science has been called in to devise a commercial application of the wave length of light as a standard. As a standard of length the length of a wave of light is admirable. It is a standard which cannot change with time, which can be duplicated anywhere in the world at any time; one which cannot be stolen, lost, or destroyed, and one which is susceptible to a greater accuracy than the standard meters or yards deposited in Government institutions.

* * *

Refinements in manufacture and the consequent refinements in gauges, etc., have reached such a stage that accuracy approaching the millionth of an inch has been possible. It is interesting to visualize the magnitude of a millionth of an inch. For instance: If we will visualize a round piece of steel one foot long, projecting horizontally from a vise and one-half inch in diameter, and a common house fly alight on the end of the bar, the conditions are such that the bar is deflected or sprung downward by the weight of the fly approximately one millionth of an inch. Engineering experience and observations with light waves prove this fact.

* * *

The effective pulling power of a belt is the difference in tension between the tight and the slack sides. Thus it is obvious that the greater the grip of the belt on the pulley, which increases proportionately with the arc of contact, the greater is the power that it will transmit. Hence it follows, that a belt running slack provided it grips the pulley firmly, will give a better grip over a greater arc of contact than a tight belt. Some forms of belting possess less elasticity and resiliency than others. The value of a pliable belt lies in the fact that the tension on its slack side may be decreased in a much greater degree than when a hard belt is used.

* * *

A Good Testimonial

We don't take in washing, but here's a story on the sales department. The other week a lady called up and asked to have an electric washing machine sent up on free trial, as we were offering at that time.

An attendant went along with it, and he doffed his coat and got to work on the wash. In no time the work was done, and then milady called us up and said:

"Thank you so much for the washing machine. I was leaving to-night for Calgary and I could never have got my washing done. Will you please send up for it before 5 o'clock?"—B.C. Buzzer.

* * *

Paper has been used extensively in Germany for driving belts and it is interesting to know that knitted or plaited belts of paper yarn have been found to stretch more than those of woven fabrics, the warp threads in the latter running straight. Woven belts are most suitable for steady-running machinery at moderate speeds, but are liable to wear away at the edge on stepped pulleys and when frequently changed from fast to loose pulleys and vice versa by belt forks, unless the latter are provided with anti-friction rollers. Single ply woven belts are only about half the strength of those of equal thickness made by lapping several layers of fabric together. A force of 10 H.P. can be transmitted by a 4-in. belt. The belts are made of paper alone or with a core layer of cotton or wire mesh, secured by sewing the inlay, reducing the tendency to stretch and increasing the working life of the belt.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

Readers are invited to send in answers to these problems, as they have been chosen for their interest and application to the practical side of power plant operation.

Perhaps you, too, have some pet problems, or hard nuts which you would like to ask your fellow engineers; if so, send them along for the benefit of others.

Answers, together with the original question, will be published in the issues following the appearance of the question.

Questions Before the House

35. What surfaces, owing to their shape, require no bracing to resist an internal pressure?

36. Classify the stays used in bracing boilers?

37. How are crown bars usually constructed?

38. What means are adopted to give warning when a screwed staybolt breaks?

39. State how the crown sheets of combustion chambers of marine boilers are generally braced?

40. How are the tube-sheets of high pressure boilers braced?

41. How are stay-tubes fastened to the tube-sheets?

42. What is an Adamson ring joint?

43. What good feature is embodied in corrugated furnace flues?

44. Explain the purpose of boiler tubes; state by what process they are made and how they are designated.

45. What process of manufacture produces the best steel boiler tubes?

46. State the purpose of a combustion chamber?

Questions Answered

Question 29. Explain the purpose of the steam dome. (b) How are steam drums connected to the boiler and what provision is made in the latter case for expansion?

Answer (a)—It forms an auxiliary steam reservoir. (b) In the case of a single boiler, preferably by one nozzle placed in the centre; in the case of a battery of boilers the header is usually connected to each boiler by a curved pipe sufficiently long to permit free expansion and contraction.

Question 30.—Explain the purpose of the mud drum.

Answer.—As implied by the name, it is a receptacle for the collection of mud and sediment.

Question 31.—What is the purpose of manholes, and how should they be placed so as not to weaken the shell unduly?

Answer.—To admit a man to the inside of the boiler, manholes should have the long axis parallel to the girth seams when placed in a boiler shell.

Question 32.—How are steam domes attached to the boiler and what are the advantages of properly constructed dome bases?

Answer.—(a) Either by flanging the dome body, or by using a dome base, and riveting. (b) They form an excellent means of reinforcing the boiler shell, and are strong where a flanged dome body is weak.

Question 33.—Explain the purpose of nozzles as applied to boilers?

Answer.—They serve to reinforce the sheet and form a convenient means of attachment for pipes and fittings.

Question 34.—Explain the purpose of stays or braces.

Answer.—They strengthen a plate not strong enough in itself to resist the pressure.

THE PERFORMANCE OF THE MOTORS THAT CROSSED THE ATLANTIC FIRST

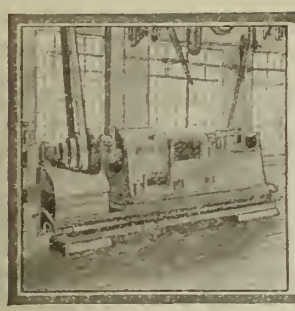
The crowning triumph for the Rolls-Royce aero engine is the first direct Atlantic flight, accomplished in 15 hours, 57 minutes, on a Vickers "Vimy" plane. Not the least remarkable part of the feat is the high average speed maintained, viz., 117½ miles an hour. Evidently the two Rolls-Royce engines fitted to the Vickers Vimy plane must have worked perfectly throughout the 1,880 miles flight.

It has been calculated that if the Atlantic crossing were completed in 20 hours by one Rolls-Royce engine running at an average of 1,800 revolutions per minute, its performance would be as follows (in a two-engined plane such as the Vickers Vimy the operations would naturally be doubled): Each engine will make 2,160,000 revolutions, and each piston will travel up and down the interior of its cylinder a total distance of 440 miles. As the Rolls-Royce engine has 12 pistons they will in all travel 5,280 miles. The valves will be operated some 25,920,000 times in each engine, the magnetos and sparking plugs having to deliver the same number of sparks for the ignition of each engine.

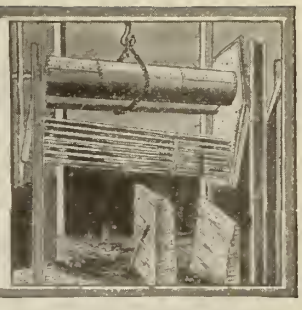
The recent history of the Rolls-Royce aero engines discloses one or two very interesting facts.

On Nov. 11, 1918, when the armistice was declared, there were in possession of the R.A.F., Rolls-Royce aero engines of a total horse power of over 1,000,000, which far exceeded that of any other make of aero engine in use. Previous to armistice day, Nov. 11, 1918, there had been constructed 122 Handley-Page bombers of which no less than 113 were fitted with Rolls-Royce engines. Prior to the same date, 1,524 complete Bristol Fighters had been delivered, of which number 1,364 were also equipped with Rolls-Royce engines. Rolls-Royce engines were used exclusively in the planes of the London-Paris Government courier service for the conveyance of the ministers, officials and despatches to and from the Peace Conference, the speed record between London and Paris, viz., 75 minutes, standing to the credit of the Rolls-Royce aero engine. The only two aeroplanes which have flown from England to India were both fitted with Rolls-Royce engines.

When a steel article with a metallic coating is scratched or abraded so that a small area of steel is exposed, the two metals will, in the presence of atmospheric moisture, form a galvanic couple or cells in which a current will be set up. The metal, which is electro-positive to the other, will be oxidized, while the electro-negative metal will remain uncorroded. When the coating is zinc, it is the zinc which will be oxidized. If, however, the coating be tin, which is electro-negative to iron, the steel will be attacked. Therefore tin as a protective coating is useful only so long as the coating remains everywhere continuous. Aluminum makes a good protective coating for steel. In the method called calorizing the metal object is placed in a mixture containing aluminum and heated up to 900 to 950 degs. C. By this means a coating of aluminum which penetrates into the iron is obtained.



NEW POWER PLANT EQUIPMENT



GASOLINE MOTORS FOR STATIONARY WORK FOR DRIVING CENTRIFUGAL PUMPS AND ELECTRIC GENERATORS

The Sterling engine, manufactured by the Sterling Engine Company, Buffalo, New York, and designed for driving centrifugal pumps and electric generators, a development of their marine product, has been manufactured for over 14 years. The racing engine, built by this company, has held the world's speed record for eight consecutive years.

The records made by the motors, and the reputation they have gained in the marine field for exceptional power and longevity, has led to the redesigning and adaption of the engines for stationary work, and to-day there are numerous units installed in townships, villages, and manufactories as standby plants for fire protection; driving centrifugal pumps and generators. The motors are admirable for this service, as they develop their rated power at a speed most desirable for the work.

Neat enclosure of all moving parts of the models FC and EC is arranged in the design, and there is unusual provision for accessibility. All covers are easily removed and attached, and ample space is provided in which to make adjustments if required. The engines are remarkably smooth running and quiet, as vibration has been practically eliminated. Longevity is assured through the extensive use of drop forgings for camshaft and connecting rods, and for bearing caps, crankshaft and camshaft gears, in addition to which bronze and aluminum castings of great tensile strength are specified throughout the motors, the material being the best procurable. The manufacturing of such engines requires up-to-date machinery and efficient machine shop methods, and in Sterling's accurate dimensions are adhered to so that parts ordered in replacement will always fit properly. The testing is rigorous and severe, and the motors are "run in" a considerable time before shipment.

The models FC and EC 17-25 h.p. motors incorporate a hollow crankshaft force feed lubricating system, oil being pumped to all main and connecting rod bearings through the crankshaft, admittedly the most advanced and efficient system in use to-day. An oil sight gauge and an oil pressure gauge are provided, so that one has a constant check on the oiling system.

The equipment of electric starter and electric generator, with battery, assures power immediately to meet any emergency. This power is constant as the motors may be depended upon to run satisfactorily for long periods at maximum r.p.m. under full load.

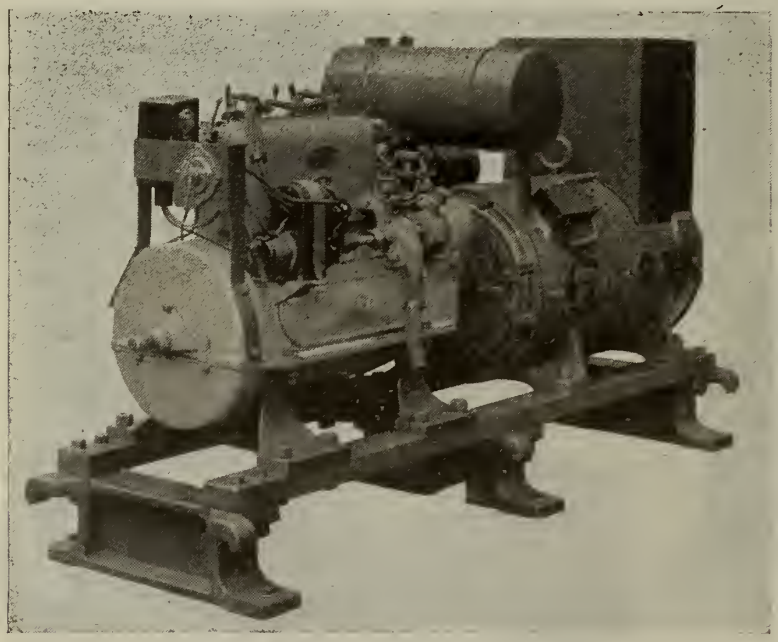
*Regular equipment includes electric starter generator (single unit).
‡Regular equipment includes electric starter-and generator (2 units).

Model FC motors having T head cylinders are regularly designed to turn anti-clockwise facing the flywheel end,



STERLING ENGINE DRIVING GENERATOR.

but can be furnished for clockwise rotation if desired The drive is taken from the crankshaft, which projects from the after end of the motor, and which is machined for mounting a flexible coupling. The models DC and EC can be arranged for drive connection at either end. The EC and DC motors being of the L head type are built to turn anti-clockwise only. The construction of the base enables a simple foundation. Where a radiator is used an air-cooled exhaust manifold with an expansion joint between each cylinder casting is provided; however, a water-jacketed exhaust manifold creates less heat, and is a protection for the operator this type of manifold being installed where a supply of water is available.

THE FRACTURE OF A FURNACE WHILE ITS BULGE WAS BEING SET BACK

Expertness in setting back bulged furnaces has improved very much of late. This is probably partly due to the increasing number of cases, due to war conditions, and partly to the difficulty of obtaining plates for replacing damaged furnaces. One of two cases which ended in failure should, therefore, prove of interest as it indicates the dangers to be avoided. When the bulges are relatively slight they are usually set back cold, but when deep they are heated by fires, usually by Wells lamps, set back hot and finished-off cold. In one case during the cold finishing-off process on a bulged furnace, a circular piece of plate measuring 10 in. diam. burst out of the furnace plate. The nature of the fractured surface left no doubt that the fracture was an instantaneous one, except over a length of about 1½ in. where the edges of the plate were slightly bent. This curious piece of plate is to be seen in our museum. The following is the most probable explanation of this mishap: In 1886 I ead a paper before a meeting of the Institute of Civil Engineers in which a large number of experiments were discussed which proved clearly that both wrought iron and mild steel have a common critical temperature, usually called blue heat, because bright steel or iron changes color through straw to purple or blue, at which temperature the material, although softer than when cold, is in a rotten condition and usually breaks if bent. If the bending be stopped before either breakages or cracks occur, and if the sample be put aside for a short period and the bending continued, or the sample straightened, then it is almost sure to break. Other mechanical manipulations while the steel is "blue hot" will also impart to it permanent brittleness. Thus on the occasion of the reading of the above paper, a bar of mild steel about 1 in. wide and ½ in. thick had been bent double at one end while cold in order to demonstrate its ductility or toughness, the other end of the bar had been polished and warmed between heaters until it commenced to change color from straw to purple and blue. While at this temperature it was placed under a steam hammer and reduced in thickness from ½ in. to ⅜ in., and was then laid aside for the meeting, at the end of which it was struck against a small anvil and broke in two. The ends of this sample were preserved and retested after waiting about 30 years, when they were still found to be as brittle as at first. Evidently age nas no beneficial effect on improperly worked steel; it can only be restored to its originally good condition by annealing. These experiments explain why the application of heaters to flanges, and other parts of boilers which have to be slightly bent, very often leads to cracks, which are called mysterious, because the true cause, the heaters, are either not mentioned or have been forgotten. Now what had happened in the present furnace mishap was very simple. The bulge had been heated by a Wells lamp. The centre was said to have been red hot, and there must therefore have been a circular zone over which the temperature was a "blue heat" during the time that the bulge was being pressed back. The setting back appeared to be perfectly satisfactory, but next day it was thought that a further improvement could be effected by re-applying ram pressure on the cold plate, with the result that the plate fractured in a circular line through the zone which had been made permanently brittle by being bent while "blue hot." It is therefore evident that in future, if furnace bulges have to be heated before being set back, they should be re-heated after they have been set back.

The annual output of thirteen billion gallons of petroleum in the United States consists of 1,800,000,000 gallons of kerosene and about twice as much gasoline, the remainder being gas oil, distillate and light and heavy residuals.

Where great power is applied slowly, particularly when space is at a premium, the worm-and-wheel drive is seen at its best. Another advantage of this type of drive is the ease with which it can be kept oiled. Perhaps greased would be a better term because the worm frequently works in grease. The whole drive is usually enclosed in a grease-tight box, though which passes the driving shaft.

* * *

In a certain plant the technical magazines which are received are first read by the engineers in the office. They are then placed in a box made especially for this purpose, at the employees' entrance. Any worker may take one at a time home, and after reading it, return it to the box so that other employees may read it. This scheme is worthy of more general application.

The Operators' Point of View

POUNDS OF AIR REQUIRED PER POUNDS OF STEAM GENERATED, INSTEAD OF POUNDS O FAIR REQUIRED PER POUNDS OF COAL

Those who have not given this matter any thought would do well to analyze the following:

After a little experimenting with com mon draft gauges, I found that the quickest action of the liquid in the tube took place when they were connected up as shown by enclosed sketch. I noticed that a very small hole in the fuel bed, or by opening the fire-door slightly, the action of the liquid in the tube was almost instantaneous. It then struck me that some means of measuring the amount of air admitted to the furnace would be of more value than a CO_2 recorder as a guide to the fireman, due to the fact that its action would be much quicker: But herein the problem that confronted me was that some means of knowing the amount of coal being fed to the furnace, the B. T. U.'s contained therein, etc., must be known.

Well, bearing in mind that the B. T. U.'s in the coal is the direct means of generating steam, and that it was and is a simple matter to make a beautiful CO_2 chart, but who is going to make the steam? It seldom happens that the fireman who makes the nice chart makes the most steam. So again with "a steam flow meter in mind" it then was only necessary to find the difference in the amount of air required in proportion to the number of B.T.U.'s in the coal.

First take the following, the two extremes of carbon and hydrogen which form practically all our commercial fuels in various ratio, we find the number of B. T. U.'s per pound of oxygen combining with hydrogen is about 7,800, while that of oxygen combining with carbon is about 5,400 B. T. U., a difference of only about 28 per cent.

Now in actual practice we find the fuel containing the highest percentage of its combustible in the form of hydrogen is natural gas, having about 25% by weight, on the other hand anthracite coal or coke having little or no hydrogen. Figuring this out you will find that the number of B. T. U.'s per pound of air required to burn these two fuels is only about 7 per cent.

Now again figuring from many of the commercial coals used in our power plants the difference in B. T. U.'s developed per pound of air is between 2 and 3 (%) per cent., say 2.5 per cent., which is much closer than any of the power house men expect to have the air regulated to the furnace.

Now from this it is seen that a problem presents itself, but which is quite easily solved. It is the aim and object of everyone dealing with the generating of steam in a boiler by the use of coal to transmit to the water in the boiler the largest possible number of B.T.U.'s contained in the coal. The most of this work depends on complete combustion, which of course depends on the amount of oxygen entering the furnace, consequently the amount of air.

Now, as before stated, the number of B. T. U.'s developed from the ordinary fuels per pound of air vary only 2.5 per cent., it stands to reason that the pounds of air required per pounds of water evaporated or steam generated must be in very close relation.

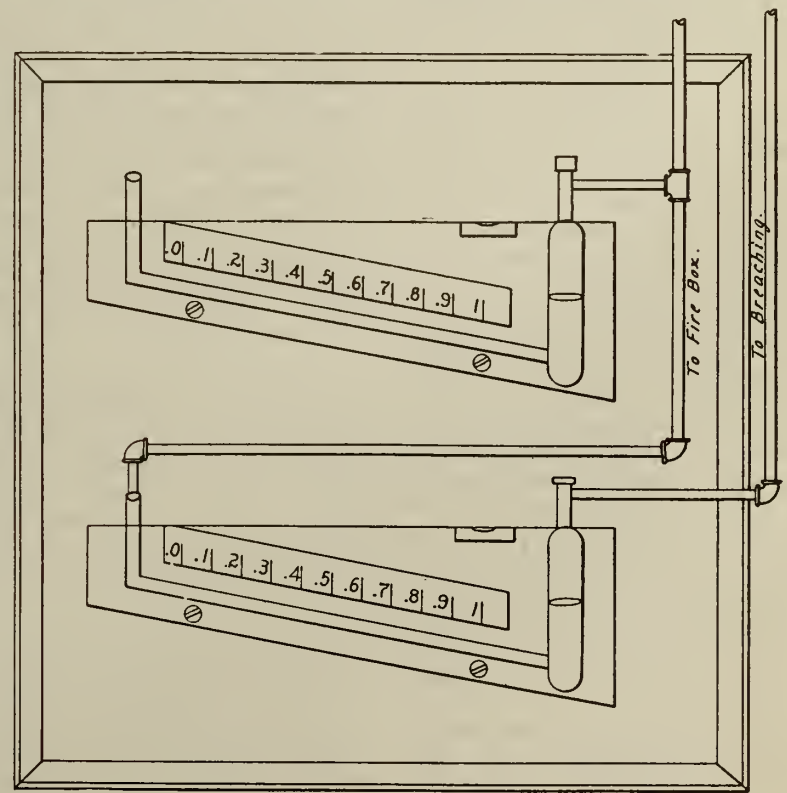
Or in other words the amount of air required per B. T. U.'s developed from any commercial fuels has a direct bearing on the number of pounds of steam turned out. And any variation from the above means a loss of efficiency in the boiler. This of course holds true only when the boiler, etc., is in good order, but once the highest efficiency has been established and the combustion in the furnace has been found to be perfect, or nearly so, "there will be an exact amount of air required in proportion to the steam generated regardless of the character or quality of the fuel." "And any variation from the above will result in a loss of efficiency."

There is now manufactured a boiler meter, and which has been on the market for about three (3) years, that measures the flow of air to the furnace, the flow of steam from the boiler and records the temperature of the flue gases. Also if desired can be fitted with a pointer that will record the condition of the fire. So in conclusion I would suggest that anyone interested in boiler and furnace efficiency would do well to analyze the above and if found as stated, which they no doubt will, can not do otherwise than recommend the use of these "Boiler Meters," as long as the word "efficiency" is used in the boiler room.

—F. F. McNeil.

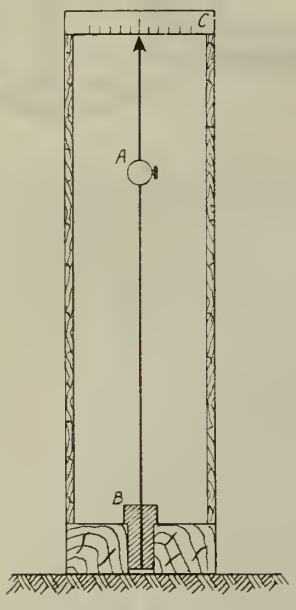
A HOME-MADE SEISMOGRAPH

Something somewhat out of the line of POWER HOUSE work, but that is,



CORRECT METHOD OF CONNECTING DRAFT GAUGES TO A HAND-FIRED FURNACE.

nevertheless, very interesting and can be made by all power house workers is a very easily made, simple seismograph. It is quite as sensitive as an expensive factory-made one. Of course, it makes no written record; neither will it show a horizontal shock. The raising or lowering of the ball A will lengthen or



SEISMOGRAPH.

shorten the time of the stroke. The upright is a piece of spring steel wire, firmly fastened at the bottom. All the joints on the frame must be made rigid, so that none of them will absorb any part of a vibration of the earth. The least earth vibration will cause the point at C to move over quite a space. It must be remembered that the seismograph must be placed upon the earth, or on a solid foundation in direct contact with the earth.

JAMES E. NOBLE.

PLASTER OF PARIS FOR GROUTING

The grouting under one of the main bearings of a twin engine broke down and further tightening of the anchor bolts proved of no use.

As the engine could not be shut down long enough for concrete to be depended on to set hard enough, resort was had to plaster of paris.

The men who undertook to do the grouting had never handled the stuff before, so they mixed a batch big enough to do the job, with the result that it "froze" on them before they got nicely started. Their method of working was revised and the grouting poured. It held so well that the other side was done also.

The disadvantage of the plaster is that it must be handled so quickly. Only a quantity that can be poured from the dish or pail immediately on mixing should be prepared at one time. Plaster mixed with a little more than half its weight of water will make a paste that will not run. Additional water is necessary to make it suitable for pouring.

Its advantage lies in the fact that it sets quickly, making it suitable for hurry-up jobs.

As for its strength there need be no worry, as it will stand a pressure of 500 lbs. per sq. in., one hour after pouring and in twenty-four hours it will stand over 1,000 pounds, finally reaching a strength of over 2,300 pounds.

R. McLAREN.

POWER PLANT KINKS AND OTHERS

By J. E. McCormack

When two or more bicyclists are out riding and one meets with an accident which disables his front wheel it is sometimes possible to remove the damaged wheel and its mudguard, then remove the mudguard from the rear wheel of the other or one of the other bicycles (which we will call No. 2) and slipping the front forks of No. 1 straddle of the hind wheel of No. 2, attach both pairs of forks to that wheel (that is, its own pair and the front pair just mentioned). This makes practically a three-wheeled tandem. Both riders can thus ride and pedal, but the rider in front must steer for both. The two mudguards and the damaged wheel may be carried along as excess baggage. It may not always be necessary to remove the two mudguards. It depends on how much room there is after both forks have been placed on the one wheel. This method is not original with me. It came to me through a machinist, but whenever I have mentioned it to members of the bicycling public it has been received as though new information. It may, however, be well known in some sections.

* * *

To prime a pump that has a suction hose on, I have seen this method succeed on the first trial after a lot of time had been fruitlessly spent trying to prime from above by pouring water into the pump through a tee on the discharge pipe connections.

The lower end of the hose was raised to the level of the top of the pump and the whole filled with water. then when starting the pump the hose was allowed to drop into the normal position below. In future trials I never knew this method to fail.

Another method, but used in connection with a hoist (as in prospecting, etc.), is to attach a tub of water to the cable of the hoist and raise it to the level of the pump, then with the pump hose coiled up in this, start the pump and when it begins to take water properly lower the tub quickly into the water below by the aid of the hoist—the hoistman acting on the pumpman's signals.

* * *

A suitable sized iron hand wheel taken from an engineer's old globe valve can be used when boring small holes by hand. Bits with tapered square shanks to fit a carpenter's brace are used and the shank inserted in the square hole in the hand wheel. I like this better than a gimlet to bore with. All makes of valves of one size do not have hand wheels exactly alike, but generally a wheel from a ½-inch valve is suitable. The hole should be large enough to take a good hold on the bit shank but not large enough to let the shank pass through far enough to chafe the palm of the hand.

* * *

When putting a cork into a bottle one generally gives it a little twist in one direction. This gives the fibres a set or trail backwards and when removing the cork again, twisting it in the opposite direction to which it was twisted while inserting tends to give these trailing fibres a slight expanding clutch action, whereas twisting in the same direction as when inserting maintains the trailing position of the fibres and so the cork comes out easier accordingly. I have found the same rule to apply to metal parts which screwed together. When stuck they will sometimes start by turning on them with a wrench in such a way as to, if possible, screw them further in when they had already refused to budge the other way without danger of breaking. I have used this kink occasionally for several years and believe that it applies more especially to brass than to iron and least to steel.

* * *

One who works more in metal than in wood, but sometimes in either or both, occasionally bumps up against a small job in wood-working where a fine-toothed saw is desirable but owing to being seldom required is not purchased. In such cases a hack saw for iron is more apt to constitute a part of the outfit. This was the case with me and I tried the hack saw by way of experiment. The results have led me to use it several times since in small jobs of fine work in wood. It sticks a little sometimes in basswood but in most woods, especially the hard woods, it works very well. If it has been used for metal previously it must be cleaned to avoid discoloring the wood during the first few cuts. This is not recommended as a substitute for a fine-toothed wood hand saw if there is enough fine work to make it worth while keeping the proper saw on hand, but it may be better than buying a new saw to seldom be used. The hack saw cannot take the place of a medium or coarse-toothed hand saw.

Figures have been given out showing the way in which costs of running the British railways have been mounting up. The present estimate of increased cost in working the railways during the financial year ending March 31, 1920, as compared with 1913, was from 104 to 109 millions, made up of war wages and other concessions, 57 millions; 8-hour day and new concessions recently gratified or still under discussion, 20 to 25 millions; and extra cost of materials and coal, 27 millions.

Care and Management of Lead Secondary Cells

By S. BUTLER

FROM a careful study of the chemical action in a lead storage cell published in a previous issue of POWER HOUSE, and the physical results of that action, one should be able to determine what treatment such a cell should get in order to obtain the best results, and the most efficient service. There is no piece of a power plant equipment that will deteriorate at so rapid a rate as the lead storage on secondary cell. The main points to be avoided are the following:

(1) For rapid charging and discharging.

(2) Use of impure electrolyte.

(3) Use of too dense or too light electrolyte.

(4) Overcharging.

(5) Overdischarging.

The disregarding of any one of these five points means disaster to the battery sooner or later, most likely sooner. A battery attendant should have some idea of elementary chemistry at the least, as well as the electrical side of the work. We will now take up the five different points in their rotation.

(1) Too rapid charging and discharging will lower the ampere hour capacity of the cell, due to the chemical action being too violent. The active elements

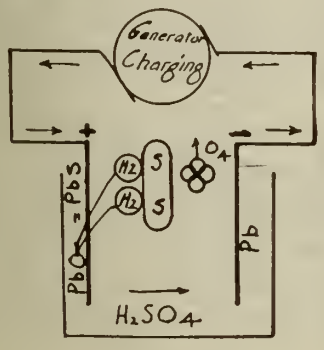


FIG. 1.

are not properly deposited on the plates and a deposit is likely to be thrown down in the bottom of the cell; this deposit, getting too high, would come in contact with the bottom of the plates and give trouble by short-circuiting them. If at any time this should occur the plates would have to be taken out and the deposits removed. This means a considerable amount of labor and a loss in the use of the battery, which cannot always be put out of commission.

Too rapid discharge. In the previous issue, diagram one should convey the thought that lead sulphate, $PbSO_4$, plus water (H_2O) is being formed, and if the lead sulphate is formed too rapidly it would be uneven in its formation, and the expansion not being evenly distributed the plate would buckle and loosen the active material, causing it to fall from the lead grid, and to come in contact with the other plate. This would give serious trouble. Or it may form a deposit of $PbSO_4$, lead sulphate, over the active material and the cell will become dead. It also lowers the density of the electrolyte due to so much water being formed. Manufacturers of storage cells usually allow a capacity of from 50 to 60 ampere hours per square foot of positive plate area, counting both sides of the plate. This capacity is computed on an eight-hour charge and discharge rate, which means that the normal rate of charge or discharge should be $\frac{50 \text{ to } 60}{8} = 6$ or 7 amperes per square foot of positive plate area, so you could take 6.5 amperes per square foot as a normal point.

Point No. 2. Use of impure electrolyte. This is where the operator would find a knowledge of chemistry a good asset. We will take up the acid part of our electrolyte first. In the manufacture of sulphuric acid, after it passes from the iron pyrites, FeS_2, to sulphur dioxide, SO_2, to the SO_3 stage, it is formed entirely in lead chambers and therefore carries with it a certain amount of lead sulphate, $PbSO_4$. Chemical pure sulphuric acid should test 1.84, temp. 59°F. Lead sulphate can be detected by distilling a small quantity in a test tube over a bunsen burner; the lead sulphate will remain at the bottom of the tube. Lead sulphate is slightly soluble in concentrated sulphuric acid, and the dissolved portion precipitates upon diluting the acid with water. Lead sulphate dissolves at a common temperature, 1 part $PbSO_4$ to 22,800 parts pure water, and is less soluble in water containing sulphuric acid. Lead sulphate can be removed by allowing the electrolyte to remain still for forty-eight hours after mixing the acid with water. Care should be taken to always put the required amount of water first, then add the acid, steadily stirring with a stick.

We will now consider the water in the electrolyte. Special attention should be given to this part of the electrolyte. Mostly all water contains some soluble foreign matter, mostly alkalies. Distilled water only should be used and filtered water avoided. Filtration being a mechanical operation, will only remove the suspended impurities. Any foreign matter held in solution can only be taken out by distillation. For example sodium coming in contact with sulphuric acid would form sodium sulphate, Na_2SO_4. Lime would form calcium sulphate or gypsum, $CaSO_4$. Traces of copper would form copper sulphate or blue vitriol, $CuSO_4$. Traces of iron would form ferrous sulphate or green vitriol. These are soluble salts. The latter two would cause local action in the cell.

Point No. 3. Too dense or too light electrolyte. The density of the electrolyte largely depends upon the conditions under which the battery has got to work. Example: A battery kept on float that is being run in conjunction with a charging generator, as a station control, or as a booster set for traction work. Such a battery could have a much

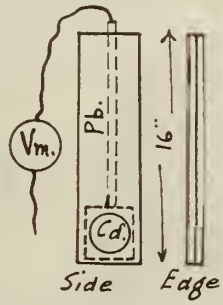

FIG. 2.—CADMIUM CELL TESTER.

denser electrolyte, because a battery under these conditions would never get a heavy discharge. And if at any time it should, it would not have to stand in that condition for any length of time. The advantage the battery would have is, it would have a higher E.M.F. or voltage and a decreased internal resistance; also a better discharge rate. If your working conditions are such that the battery may have to stand for any length of time in a discharged condition, then a lighter electrolyte is better, as the chemical action of weaker acid would not be so violent and the sulphating less. But the E.M.F. or voltage would be lower with an increased resistance and the discharge rate not so good; so it is well to know under what conditions the battery has to work.

Point No. 4. Overcharging. By referring to diagram No. 3 of the previous article, it will readily be seen that the H_2O part of the electrolyte has been formed up with the $Pb(SO_4)$ into sulphuric acid, H_2SO_4, leaving us with a positive plate of PbO_2, lead peroxide, and a negative plate of Pb or spongey lead, PbO_2 being the highest oxide which it is possible to form. This is where the battery should come off charge, but for example we will still keep on charge. The accompanying diagram will convey to you some idea of what is going to happen. The plates will turn a very black brown or nearly black in color. Re diagram S, sulphur combines with H, hydrogen, in the ratio as hydrogen and oxygen (H_2S) (H_2O) and form H_2S hydrogen sulphide. Hydrogen sulphide readily attacks lead compounds and forms PbS, lead sulphide. Hydrogen sulphide being a highly soluble gas would not be noticeable in the room. This action in time would ruin the plates.

Point No. (5) Overdischarging. This is a point that wants very careful atten-

Fifty Subscriptions from One Firm

THE International Business Machines Company, of which Mr. Frank E. Mutton is vice-president and general manager, subscribed to 10 copies of THE FINANCIAL POST some months ago—these copies to go to their travelling salesmen. Now this company has increased the number of these subscriptions to 50 because the results of the experimental subscriptions have proved so satisfactory.

FRANK E. MUTTON

Mr. Mutton explained that the object of putting THE POST in the hands of the men of his company was to keep them intelligently acquainted with general business conditions in Canada. He said he knew no better paper than THE POST for the purpose. It would seem that his men have responded fully to effort made to keep them well informed about Canadian business affairs—so much so that the management have added 40 other men to the original 10 to receive THE POST.

When Mr. Mutton was with the National Cash Register Company as its Canadian manager, he was the king of all managers in the matter of sales records. In this position he achieved a big reputation built on solid achievements. He learned salesmanship in a school where competition was of the hottest kind, and where the competitors were brilliant men. Giving Mr. Mutton full credit for superior personal qualities and energy of the most ardent kind, it is taking nothing away from him when it is said that not a little of his success was due to his intimate and sympathetic knowledge of the other man's business. And he taught the men associated with him as salesmen to know the point of view and requirements of the men they called on to sell machines to.

As vice-president and general manager of the International Business Machines Company, Mr. Mutton is putting into operation an idea used by him in past days with brilliant results—he is causing his salesmen to know the business and requirements of their prospective customers. To establish points of contact swiftly and surely is one of the open secrets of successful selling.

In the case of **your** solicitations of customers and desired customers, it is excellent strategy to have your salesmen so well informed about business conditions generally, and about the interests of the men they canvass, that they will be able almost instantly to relate their proposals to the interests of the buyer. When a salesman shows himself intimate with the interests or business or objectives of the man whose order he wants, he is immensely strengthened as a salesman, and his percentage of successful canvasses goes steadily up.

Our definite suggestion to you is: Subscribe to THE POST yourself, and learn from its pages how your salesmen or executives can draw power from this newspaper. Then, having acquired the sought-for knowledge, subscribe to THE POST for each man in your service who can profit you by knowing what is in THE POST each week. If Frank Mutton and other prominent executives are making a success of THE POST as a salesman's aid, it is reasonable to suppose that other managers of salesmen and executives can likewise employ THE POST as a producing agent. And so we ask you to sign and forward the coupon below.

- - - -

tion as it will be found that the electrolyte is getting lighter and the PbO_2, lead peroxide, is being burned into lead sulphate, PbSO. For example, the specific gravity at full charge being 1.215 should not be allowed to drop below 1.195, a drop of 20 points, and the voltage would be about 2.2 and should not go below 1.8 or 1.9. Voltage readings should be taken when the battery is either on charge or discharge at the normal rate. The normal discharge rate is preferable, as there will be less liability of discharging too low. Voltage readings taken when a battery is not working, that is on open circuit, give no indication as to the condition of the plates, as the voltage does not depend on the size of the plates, so long as there was any lead peroxide on one plate and spongy lead on the other, the electrolyte about 1.200, the voltage readings would be about 2.2 volts, you would be getting the potential differences between the plates. There is one point of warning for the safety of the attendant, and that is he should never under any circumstances carry an open flame or strike matches in the battery room.

The Use of the Cadmium

Voltage readings taken with the cadmium stick are the most accurate readings. The voltage on a fully charged cell from cadmium to lead peroxide is 2.5 volts, and from cadmium to spongy lead zero. With the use of this stick a faulty plate can be localized in a cell. The accompanying diagrams give the construction of the cadmium stick. Procure 1 piece of hard rubber one and a half inches wide, 1 sixteenth of an inch thick, 1 piece of cadmium ⅝ by ¾, sweat or solder to a thin lead wire about No. 14 or 12 gauge, drill ½ inch hole near the bottom of the hard rubber, equal distance from the centre to one side of the rubber. Then cut a groove marked by dotted lines, to receive the lead wire; the lead wire could be hammered a little flat for convenience. Mark the centre of the hard rubber at either ends as a guide. Put the hard rubber into boiling water, keep it there until it becomes pliable. You will then be able to bend the hard rubber in the centre, where you put the marks at either end as your guide. Put your cadmium and lead wire in its place and squeeze together between two pieces of board in a vise or clamps. Should the rubber begin to set hard, place it again in the boiling water with its contents and resume the pressure. You should have no trouble in making one of these stick, and you will be well repaid for your trouble, as no battery attendant's kit is complete without one.

BOOK REVIEWS

The Construction of Graphical Charts, by John P. Peddle. The McGraw Hill Book Co. Price $2

Much of the work of calculation done by the engineer and designer is in the repeated calculation of a limited number of formulae to a variety of different conditions, which involves merely the substitution of different variables in identical equations. Any mechanical means for performing this operation expeditiously will not only lead to a saving of time and mental wear and tear but will also minimize the chances for error. Such a device is the chart or nomagram, and the present work enters into its construction in a very clear and practical manner. Believing that the subject should be particularly useful to the practicing engineer who is often a trifle rusty in some parts of his mathematics, an effort is made to simplify the mathematical treatment. A series of illustrative problems has also been worked out in detail as it was thought by the author that these would afford a clear insight into the methods and a better understanding of the difficulties likely to be encountered than would be possible from a purely theoretical analysis. In the second edition of the work now presented a chapter on the use of determinants, in the plotting of graphical charts, has been added.

Contents,—

Charts plotted on rectangular coordinates; the alignment chart; the hexagonal index chart; proportional charts; empirical equations; stereographic charts and solid models; the use of determinants.

The Electric Range Handbook; the Society for Electrical Development, Inc., United Engineering Societies Bldg., New York; Price $1.50

The handbook is a complete compilation of authentic electric information and data. Its purpose is to guide and help solve the problems of central station managers, who have realized the importance of the range load and who are contemplating the active development of this class of service. The text has been reviewed and approved by several range authorities. Chapter I takes up the characteristics of the electric range load, compares the range with other household appliances and discusses cooking rates and their justification. The problem of financing extensions and installations are also dealt with. Chapter II. deals with the electric range itself and together with its construction takes up its advantages in the home. Chapter III. is a historical resume of electric cookery and enters into the characteristics of electric heat as applied to cookery. The range load, from the standpoint of the central station. is taken up in Chapter IV. both from the standpoint of investment and also as to the characteristics of the load.

Merchandising methods are dealt with in the following chapters, selling points, advertising and maintenance also being dealt with. The last three chapters deal with water heaters, commercial cooking apparatus and general information. To those having to do with the promoting of electric range load this handbook is commended.

Electrical Aids to Greater Production; Allen M. Perry—The McGraw-Hill Book Co., Inc., New York

Eighty per cent. of the power used in making munitions has been applied electrically. The war has brought to the engineer in the industrial plant, to the chief electrician of such plants, and to the consulting engineers, who laid out and designed the electrical equipment for industrial work many new opportunities. The present volume has been written out of the experiences of men engaged in this work and the best of this practice has been assembled and compiled from articles which have appeared from time to time in the "Electrical World" on industrial problems of this nature. The material has been chosen and edited, not to make a text-book but rather a practical handbook of methods, schemes and plans, which can be lifted out and adapted to a wide variety of conditions. The ranges of subjects treated of is almost as wide as are the applications of electricity to modern industry and much useful information is presented for the engineer in charge of plant equipment. Proper records are an important part in the smooth management of electrical plant and this phase of the work has been carefully covered.

Contents, Chapter I,—General Power Problems of Industrial Plants. Chapter II. — Distribution, Transformation, Switching and Protection. Chapter III. Motors, Control, Specific Applications, Troubles and Remedies. Chapter IV.—Illumination—selection of equipment, Economies and Specific Applications. Chapter V.—Electric Furnaces, Welding, etc. Chapter VI.—Meters and Measurements as applied to industries. Chapter VII.—Handling Material in Industrial Plants with Electric Tractors. Chapter VIII.—Outdoor Substations.

The Canadian Morehead Manufacturing Company, Limited, Woodstock, have issued a cloth bound booklet giving considerable data, useful to the power plant engineer and the heating expert.

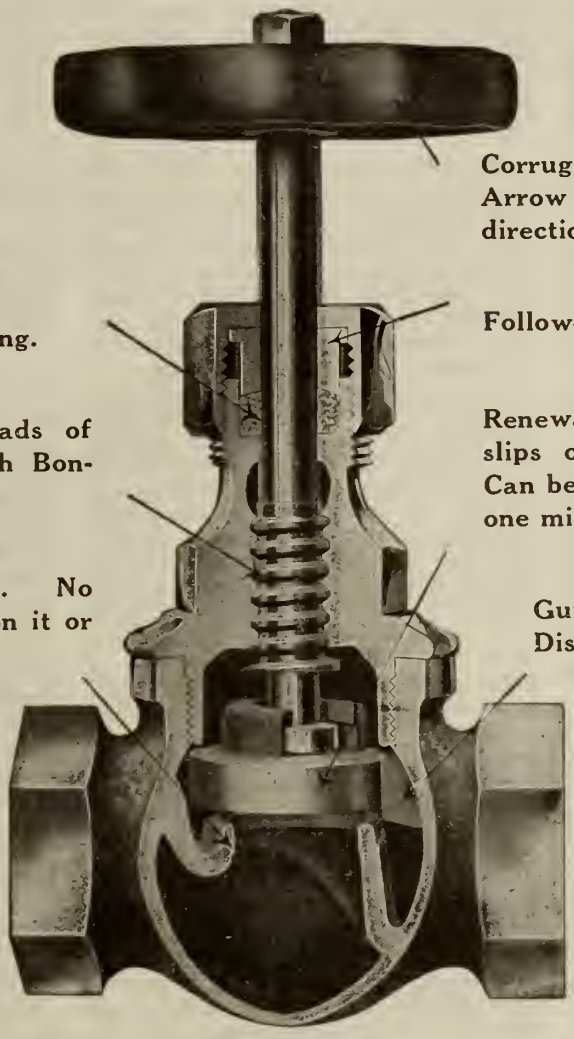
The Foster Instrument Co., Letchworth, Herts, England, have issued a very practical chart on the care and use of pyrometers. This chart, suitable for hanging up in the works, contains hints on the use of pyrometers of various types, such as radiation thermo-couple and electric resistance, and also has a useful Fahrenheit-Centigrade conversion chart ranging from 50° to 3550° Fah.

TRADE GOSSIP

Pembroke is going to have a new lighting system.

The Town of Aurora, through James, Loudon & Hertzberg, 36 Toronto St., Toronto, are in the market at once for a centrifugal pump of 750 gallons per minute capacity, to be driven by a gasoline engine.

Fairbanks Renewable Disc Valves



Corrugated Iron Wheel, Arrow cast on wheel shows direction valve opens.

Follower in Stuffing Box.

Palmetto Twist Packing.

Renewable Bakelite Disc slips over end of spindle. Can be replaced in less than one minute.

At least Four Threads of Spindle engaged with Bonnet at all times.

Guide cast on Body holds Disc centrally over seat.

Raised Round Seat. No sediment can lodge on it or injure disc.

Globe or Angle

Screwed or Flanged

The disc of the Fairbanks Renewable Disc Valve can be renewed in less than a minute without removing the valve from the line, a wrench being the only tool necessary.

Everything in Mechanical Goods.

The Canadian Fairbanks-Morse Co., Limited

"Canada's Departmental House for Mechanical Goods"

St. John, Quebec, Montreal, Ottawa, Toronto, Hamilton, Windsor, Winnipeg, Saskatoon, Calgary, Vancouver, Victoria

Plant Closes.—The plant of the Brunner Mond Company at Amherstburg has been closed down, to stay so until labor conditions become such that business can be carried on. The plant, which is a subsidiary of the Solvay Process Co. of Detroit and Syracuse, is the largest in this country. Several hundred men are affected by the unexpected development.

Ready for Operation.—Canadian Engines, Ltd., manufacturers of stationary and portable gas and gasoline engines, grain grinders and saw frames, who were practically closed down during the war, have resumed operations, and are taking on a full complement of men. They report an abundance of business in view and that the prospects are favorable for a busy time throughout the year.

Tanning Company Extends.—Advices from Kitchener, Ont., state that the Lang Tanning Company, one if the pioneer industries of the city, will make a considerable addition to its plant. This will consist of two buildings each 100 by 200 feet, four-storey brick construction. The present staff, which numbers about 200, will be increased to 300 and possibly more when the new buildings are ready.

New Power Plant.—A huge power plant is being constructed on the Winnipeg River at DuBonnet Falls, 75 miles north of Winnipeg. The Winnipeg River Power Company, backed by Mackenzie & Mann interests, are the owners. The ultimate capacity of the plant will be 168,000 horse-power, in six units of 28,000 each. The development will take three years, and will cost $700,000.

To Attend Athens Fair.—The fair at Athens, which commences on October 13th, will contain exhibits of Canadian manufactured goods. This is the result of Mr. Lloyd Harris's efforts to interest Canadian manufacturers in the possibilities of the Balkan markets. One of the methods of placing the goods before the visitors to the exhibition is by photo, and a large number of these have been sent. The invitation to attend came through the Federation of British Industries. The Canadian Manufacturers' Association has a representative who is interviewing all manufacturers whose goods might be suitable for the Balkan trade.

The United States Rubber Co., of Canada, Ltd., has been incorporated with a capital stock of $20,000,000, divided into 200,000 shares of $100 each, the head office to be in Montreal. The company will manufacture and deal in all kinds of rubber goods. The principals are Alexander Chase Casgrain, Errol Malcolm McDougall, Leslie Gordon Bell, Sadie Conrad Demers, and Edward James Waterson.

New Pulp Mill.—Advices from Bear River, N.S., state that work has started on the new mill for Clarke Bros. The buildings will consist of a pulp mill, saw mill, boiler room and machine shop.

Simcoe.—The public utilities commission is going to buy a centrifugal pump for sewage disposal work.

Chatham.—An engineer is to be engaged to go over the situation here and report on the best plan for a waterworks system.

New Pumps for Guelph.—The Fire, Light and Water Committee have recommended the acceptance of the tenders of the Goldie McCullough Co. for the installation of a 750 gallon pump with a 75 h.p. Crocker Wheeler motor, at $2,904, also a 1,250 gallon pump with 125 h.p. Crocker Wheeler motor for $3,640. The Bawden Pump Co. secured the order for a 2,100 gallon booster pump with 100 h.p. Crocker Wheeler motor for $2,621.

Dominion Foundry to Close.—The Dominion Foundry plant at Hamilton will be closed down for two weeks in July while electric ovens are installed. Not many men will be affected, as the plant has been running light for some months. It is reported that the company intends to operate rolling mills in the course of a couple of months.

Erect Fuel Factory.—The Anthracite Briquette Company will start building immediately on the new industrial site of the Toronto Harbor Commission a factory for the making of compressed anthracite briquettes. Large supplies of waste anthracite have been secured, and the plant will have at first a capacity of ten tons per hour. The rights of a patented binder have been secured from the United States. The use of these briquettes will, it is claimed, make a big saving in the cost of fuel. Some of the best brains of the chemical staff of the Toronto University have been connected with the process, and it is understood to be a first rate commercial proposition. The capital is all privately subscribed.

May Arbitrate Now.—Mr. F. G. Wallace, president of the Canadian Locomotive Company, Kingston, has replied to the letter sent him by the committee appointed by the City Council to endeavor to bring about a settlement between the company and its striking employees. Mr. Wallace, in thanking the committee for its kind offer, says that the time is not opportune for outside intervention, and continues as follows: "Had we refused to meet our employees, your committee might have been of great assistance, but our men fully understand that they can arrange a meeting with us at any time they so desire. Under these circumstances you will readily see that it is impossible for us to avail ourselves of your kind offer." The Strikers' Committee has written the Council's Committee that it is ready to negotiate its differences.

Company Reorganized.—The recent reorganization of the St. Lawrence Welding Co., of Montreal, places the control of the company in the hands of W. H. Barry and A. M. Barry, president and general manager respectively; F. E. Fox being appointed a director and secretary-treasurer. L. E. Moulton is also a director of the new firm. The plant here has been enlarged and a well-equipped machine shop added to carry out the complete repairs of all welded work. A staff of boiler makers is, likewise, a part of the new organization. Every class of welding work is carried on and the firm make a specialty of oxy-actylene and electric welding repairs. They have recently purchased a new portable electric equipment for operations between Halifax and Montreal. During the present season a brisk business has been carried on, considerable repairs having been performed to the troop ships entering Halifax.

STORAGE OF COAL AND SPONTANEOUS COMBUSTION

Coal should be stored in small quantities as near to the point of consumption as possible. Small coal piles rarely ignite from spontaneous combustion. Coal should be stored near the point of use to avoid re-handling, extra transportation and the degradation of size which follows each re-handling. For these reasons the bureau would advocate storage, so far as possible, in the bins and yards of the ultimate consumer, thus dividing the risk of loss from spontaneous combustion. If large storage piles are necessary, certain general principles must be borne in mind. The generation of heat is the result of slow oxidation of the coal surface. The oxidation is much more rapid from freshly mined coal or from freshly broken surfaces. The oxidation rate increases rapidly with increased temperature. Different coals have different oxidizing rates. These facts lead to the following recommendations:—Where there is choice of coal to be stored, that having the lowest oxidizing rate should be chosen, if known. Between two coals, that which is least friable, and therefore which presents the least total coal surface in the pile, should be selected.

The method of handling should be such as to produce the least freshly broken coal surface. The coal should be as cool as possible when piled. Piling warm coal on a hot day is more likely to produce spontaneous combustion. The coal must be kept from an extraneous source of heat. Alternate wetting and drying of coal during piling is to be avoided if possible. The fine coal, or slack, is the part from which spontaneous combustion is to be expected. Piling of lump coal where possible is therefore desirable.

In the process of handling, if the lump coal can be stored and the fine coal removed and used immediately, the practice prevents spontaneous combustion in coals which would have otherwise given trouble. The sulphur content of coal is believed by many to play an important role in spontaneous combustion. The evidence on this point is still con-

flicting, but to play safe, it is desirable to choose coal having a lower sulphur content when choice is possible.

There is a current belief that dissimilar coals stored in one pile are more liable to spontaneous combustion. The evidence on this point is also conflicting, but to play safe it is advisable to store only one kind of coal in a pile. The ground on which a coal pile is built should be dry. The foregoing recommendations are all derived from the factors affecting the heating of coal. There should be no spontaneous combustion, whatever the heating rate, provided the heat is carried away as rapidly as produced. This fact brings about the following recommendations:—

Coal piles should be made that there is ready movement of air for ventilation throughout all parts of the coal pile. This is the condition when the entire pile is made of coarse lump coal. With ordinary coal piling this is difficult. The surfaces of coal piles should be so exposed as to allow the pile to cool; or else the coal should be so stored that air circulation within the pipe is very small. When the air circulation is reduced to a minimum, as in air-tight bin, with no opening in the bottom, the oxygen of the air is soon removed and the mass of the coal lies in an inert atmosphere, except for small local circulation near the surface. Air-tight bins are usually impracticable, but the following practice is recommended to approximate these conditions:—

In making a coal pile of mixed sizes, the coal should be so handled as to make a homogeneous pile and prevent the segregation of coarse and fine coal. This frequently determines the most desirable machinery for unloading coal. It is common practice to limit the height of a coal pile, this for two reasons:—A pile too high crushes the lower layers of coal, producing more fines; the larger the pile the less the heat-dissipating surface there is exposed in proportion to the heat generating capacity of the pile. Twelve feet in height is a common limit.

Whatever precautions are taken in choice and handling of coal, provision should be made for keeping track of the temperature rise in a coal pile and for rapid rehandling of portions of a pile in case of excessive heating. In a coal pile covering considerable area, it should be so subdivided that in case of spontaneous combustion of a portion, the heat will not be transmitted to the whole pile, thus accelerating the heating of portions of the pile which normally would have remained cool.

To keep track of the temperature of coal piles, it is recommended that ½ in. iron pipe be driven vertically into the pile at distances of 15 ft. or 20 ft. apart. A maximum thermometer lowered into the pipe to varying depths will indicate the temperature of a pile opposite the thermometer.

A survey of the pile and a survey of the temperature of all parts of the pile. Actual removal need not begin during the first three months after the pile is made, and once a week thereafter until the pile has evidently ceased to heat. As soon as any portion of the pile reaches the temperature 150 deg., provision should be made for removing that portion of the pile. Actual removal need not begin until the temperate has reached 180 deg., but at these temperatures the rate of oxidation is dangerously rapid. The object of rehandling the coal is to allow it to cool below a dangerous temperature. Any method of rehandling which does not allow of cooling will only transfer the difficulty from the old pile to the new one. It is usually useless to employ water in an attempt to cool a coal pile.

Lack of provision for rapid reloading, cooling, and repiling of coal is the cause of serious loss from spontaneous combustion.

Constructed on a different principle—
Steam Trap SARCO

Wherever a marked advance has been made in any mechanical field you'll find a radical departure from the accepted practice.

This is particularly true of the Steam Trap Sarco. It is different from all others — designed on a new principle.

The Sarco automatically operates by the opening and closing of a valve controlled by a sensitive but infallible expansion element.

Leakage of live steam, breakdown of complicated parts—all the disadvantages of the old-time, obsolete, ineffcient traps —are done away with by the Sarco.

It is simplicity itself. Simplicity and reliability. Your engineer will instantly perceive the correctness of the Sarco principle.

Hundreds of thousands in use. Write us to-day for a Sarco on 30 days Free Trial and Booklet "J." No obligation.

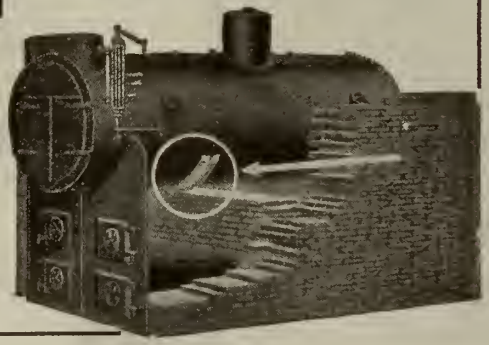
NATIONAL Boiler Girth Seam Protector

Protection means longer life and greater efficiency

If your Boiler is not Fire-cracked it eventually will be. Prevent this by putting on a National Boiler Protector. You will save cost in repairs and prolong life of the boiler. All new boilers should be protected. If your girth seam is giving you trouble at the present time, have the seam caulked up, attach one of these protectors and the seam will remain absolutely dry thereafter.



Guaranteed for one year. We make protectors for patches and all styles of boilers. For full particulars, write—

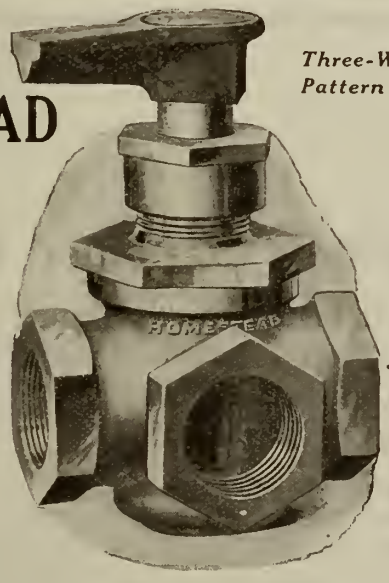
HOMESTEAD

Quarter-Turn Valves



Three-Way Pattern

Economy!
Efficiency!
Safety!

The efficient service Homestead Valves give, proves the superiority of plug cock valves over other types. Homestead Valves combine direct and unrestrained flow with simplicity and ease of operation.

Every Homestead Valve saves its own cost shortly after installation by eliminating wastes and leakages. This is an economical feature of Homestead Valves worth considering.

The harder the service, the more the safety of Homestead Valves is appreciated. Easily stand greater pressure than that for which they are recommended.

Wanted—

Engineers to contribute to Power House

THIS is a practical paper for practical engineers. It is an educational medium and out to help its readers. It is a technical school and a social meeting place combined. It is first, last and all the time an engineer's paper.

If you should meet two or three or a dozen of your brother engineers you would swap ideas—you'd tell of some idea you had worked out in your plant. Others would describe some pet schemes they had devised. And so you would be mutually benefited.

Why not make Power House your monthly meeting place? Why not describe in this paper some kink or scheme you have worked out and found successful? We will pay you for it and you, in turn, will be multiplying the usefulness of your idea five thousand fold!

Never mind polishing up your letters—just give us the idea; that's the main thing. Never mind how crude your pencil sketch may be. We have draughtsmen who will finish up your drawings so they may be reproduced.
Try this idea a time or two and see how much satisfaction you'll get out of it. Start the ball a-rolling and thus help other engineers, yourself and your paper.

POWER HOUSE, 143-153 University Avenue, Toronto

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Have The Maritimes Had Fair Play?

THE Maritime Provinces did not enter Confederation very willingly and it may surprise people in other parts of the Dominion to learn that at the present time the people of New Brunswick and Nova Scotia are not altogether pleased with the results of the bargain. There is a distinct feeling among them that the advantages of Confederation have gone to the other Provinces. In the course of an article in the July issue of MACLEAN'S MAGAZINE, Thomas M. Fraser explains why this feeling has grown and the basis for it.

This article was written for the purpose of letting the other provinces know that the feeling exists but it will be of intense interest to people in the Maritimes. Be sure to read it—"The Spirit of the Maritimes."

"The Land of National Leaders"

An article on the political aspect of the Eastern Provinces and the achievements of their leading statesmen.

"Guarding Our Coast Line"

An extremely interesting description of the measures that were taken to patrol and guard the Atlantic seaboard during the war.

Bonar Law, the man from the Maritimes, who has been the able lieutenant of Lloyd George at all crises in Great Britain, appears on the cover in a handsome three-color reproduction.

Other Big Features of the Number

"With the Snowball Brigade"

By Captain Louis Keene

Just back from Siberia—Captain Keene tells some sensational and intensely gripping things about conditions in that country which the Canadian forces are helping to stabilize. It is a record of international complications, strange atrocities and almost unbelievable living conditions.

"The Three Tommies"

By Robert W. Service

A war poem of unusual strength.

"Solving the Problem of the Arctic"

By Vilhjalmur Stefansson

The fourth instalment of his remarkable story of the five years he spent in the north for the Canadian Government, appearing exclusively in MACLEAN'S.

Three Magnificent Stories

The best fiction obtainable is found in this issue: "Owners Up," a race horse story by W. A. Fraser; "His Majesty's Well Beloved," by Baroness Orczy; Bun'cered," by Allen C. Shore.

The Review of Reviews

Here are a few of the articles in this splendid department chosen as the best published during the past month in all magazines:

Finding Husbands For Three Million Women.
Will England Become an Agricultural Country?
Germany Can be Prosperous Under the Peace Terms.
The Woman Who Wrecked the World.
The Great Lama Rides in Motor Car.
Strange Personalities at Paris.
Making All Men Equal.
Winning the Secrets of the Desert.

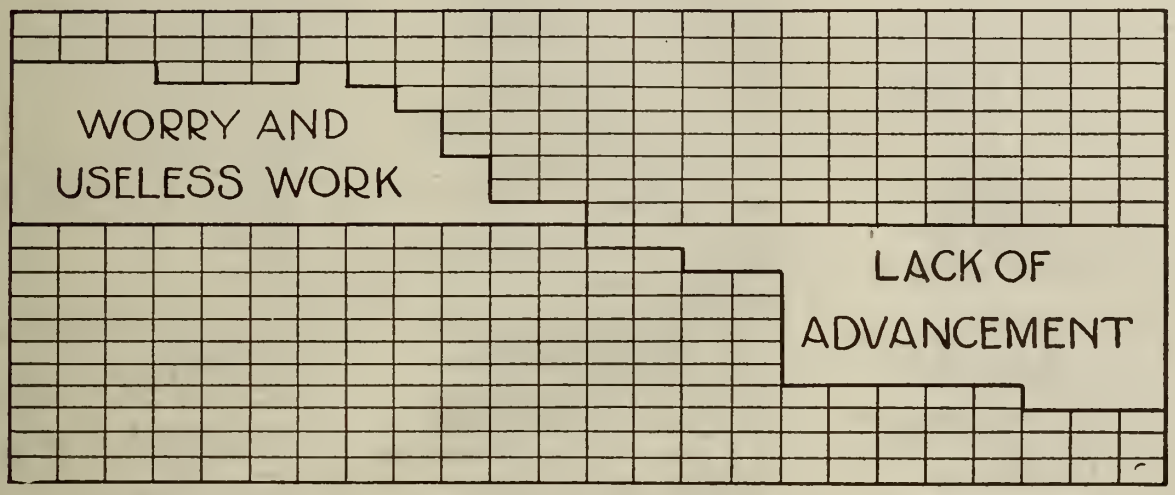
Let the C.A.S.E. Smooth Out Your Load Curve



Remove The Peaks of Worry And Unproductive Labor And Build Up The Valleys By Working For Your Advancement

A man who is thoroughly grounded in the practice of his profession, who is free from personal worry and trouble, overcomes the many difficulties besetting the path of the operating engineer with little labor and in a manner ensuring his advancement.

The successful man owes his success to a wise appreciation of the advantages and mutual help offered by association with those in the same field of endeavor. To join an association having for its objectives the welfare of the engineer in things mental and material, his advancement in knowledge and skill, his protection by provision for sickness and distress is to take advantage of an opportunity indispensable to all who hope to better themselves.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914, With Amendments Chapter 58—6, George V.

STEAM BOILERS

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G. MACDIARMID, Minister of Public Works and Highways

W. A. RIDDELL, M.A., Ph.D., Supt. Trades & Labour Branch

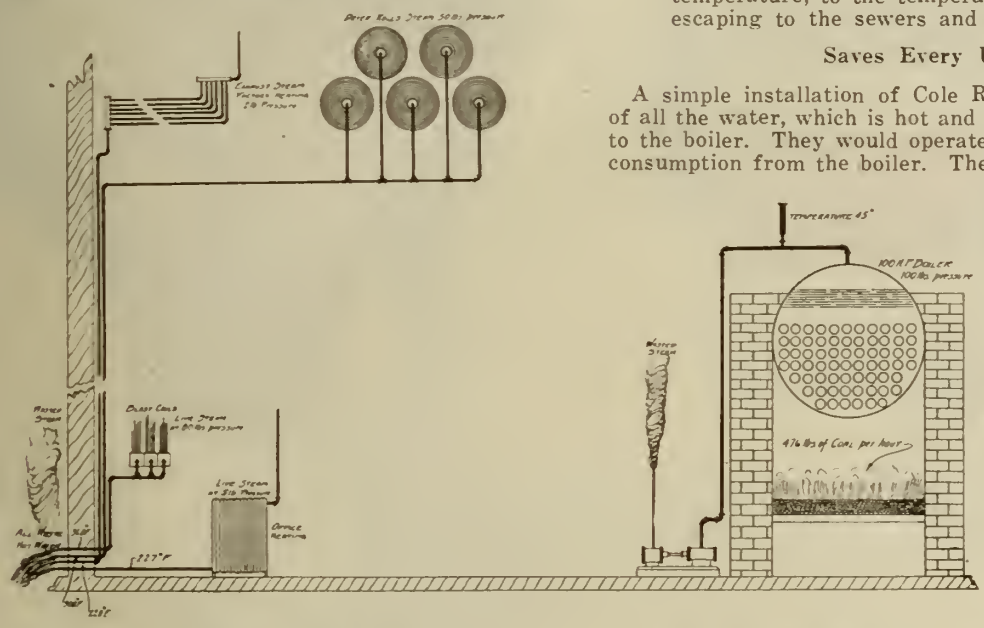
This Is To Show You How "Cole" Return Traps Save Your Fuel

Just study the diagram. Does your plant operate like this? We hope not.

You note how all the water of condensation from every source is lost. Discharged into the air, or into the sewers.

Pumps Require Steam

There is a constant loss of good hot water and steam taking place here. This lost water and steam is replaced through a Feed Pump or Injector, into the boiler.



Let Us Help You

If your plant operates under anything like these conditions as far as condensation return is concerned, we want to hear from you. If you are interested in saving fuel, in saving yourself useless work and worry ask us to have one of our condensation experts call on you.

More Data to Come

In our next ad. we will illustrate other conditions which obtain in steam plants, and which you should be aware of, where constant losses are occurring, and which only need pointing out to the Factory Executive to have them corrected.

The pump takes the water from the source of supply, and it is cold water generally.

To operate the Pump or Injector, the boiler must produce an enormous amount of steam, compared with the work done. This steam is generally wasted to the air.

Heating Cold Water Costs Money

Of course, as cold water is fed into the boiler, fuel must be burned under the boiler, in order to raise its temperature, to the temperature at least, of the water escaping to the sewers and air.

Saves Every Unit of Heat

A simple installation of Cole Return Traps would permit of all the water, which is hot and pure, being returned direct to the boiler. They would operate with practically no steam consumption from the boiler. They would replace the costly Feed Pump and by returning the hot water to the boiler, would save a considerable amount of fuel in making steam.

The Saving

Approximately, the amount of fuel which is wasted in a plant such as this, operating a 100 H.P. boiler at 100 lbs. pressure would equal 30 per cent. of the total fuel burned under the boiler.

The Cost

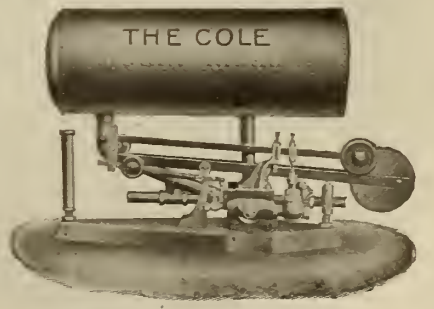
The cost of the installation in your plant would be very nominal, and under such conditions as the diagram shows, would save enough fuel to pay for itself in about three months, or less, and every succeeding three months would put a similar sum of money in cold cash in your employer's bank account.

Credit For You

Don't you think your employer would thank you for pointing out how this waste could be saved? Showing him how to save good money?

We have Bulletins, which contain interesting information to enquirers generally, and you should have them.

Write us for any further information on the "Cole" Return Trap.



Stop the wasteful Steam Plants. Install "Cole" Return Traps. There is Credit and Increased Wages in it for you.

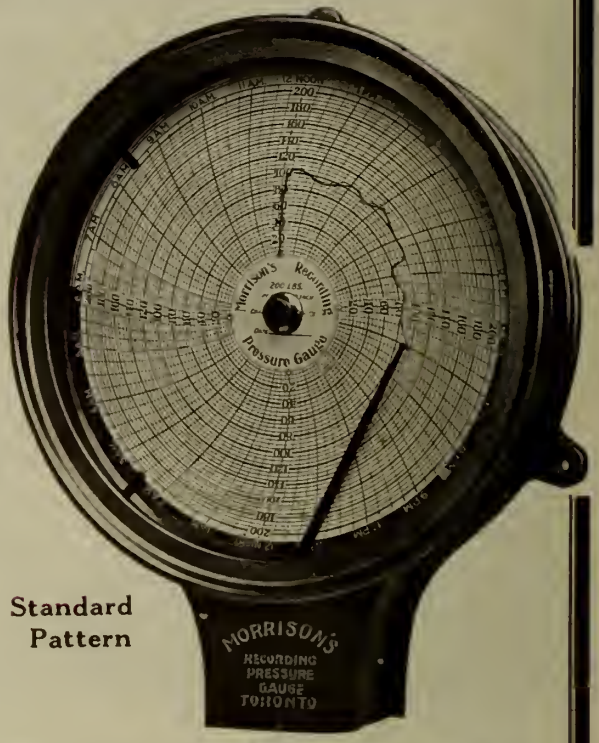
GEORGE W. COLE LIMITED

2002-4 DUNDAS STREET WEST - TORONTO, ONTARIO

Don't waste your fuel

MORRISON RECORDING GAUGES

For Steam, Air, Gas, Water and Vacuum



Standard Pattern

It is well known that fluctuating pressures mean firing that is not economical, causing waste of fuel, and possible damage to Boilers due to strain. It means loss of Engine efficiency, for, Engines are designated for a definite throttling pressure, it causes irregularity and wastefulness when Steam is used for Heating, Drying, or other purposes. Extreme fluctuation results in insufficient power, explosions, and other accidents.

The Recording Gauge gives the record of Boiler Pressures automatically in ink, independent of personal attention. It places responsibility. It gives minimum and maximum pressures, indicating just when they occur. It shows when fires are started and when banked, all details briefly, plainly, and without error.

To the Engineer, the Recording Gauge enables him to report to the owner that his duties have been performed in a faithful and efficient manner. He knows that by its records disputes and criticisms are prevented, and he can determine and analyze conditions for future guidance.

To the Owner, its installation usually results in reduced Coal Bills. It settles pressure troubles and adds to the life of boiler and equipment, in addition to which it insures safe operation.

Low Up-Keep Cost of Dominion Friction Surface Belting

Cost of maintaining equipment in the average plant is seemingly so small when compared with other costs that it is seldom considered seriously, but when totalled at the end of five years, represents a far greater expense than actual necessity demands.

Maintenance of belting is in itself an important item, because each repair means idle employees, idle machines and less production, the total cost of which is often greater than you would pay for better belting.

Dominion Friction Surface Belting is built for "service first" that its long, continuous performance may eliminate the necessity for repairs and replacements.

But it gives an added service in conserving power—the rubber that goes into it is a special friction compound that prevents practically all slipping on the pulleys, even under quick load changes.

Our belting experts are ready to help lower your maintenance costs on belting and can suggest changes that will lower your production costs.

A phone, wire or letter to our nearest service branch, places at your disposal, without obligation or charge, not only their services but the entire facilities of the oldest and largest rubber organization in Canada.

211 BOARD OF TRADE BLDG. - - MONTREAL

POWER HOUSE, August 5, 1919, Vol. XII., No. 12. Published semi-monthly at 143-153 University Ave., Toronto, Canada. Subscription price in Canada, $1; in United States, $1.50. Entered as second-class matter at the Post Office Department, Ottawa, Canada. Entered as second-class matter July 1, 1912, at the Post Office at Buffalo, under the Act of March 3rd, 1879.

Indifference to the Stop Cock!

You know what that means.

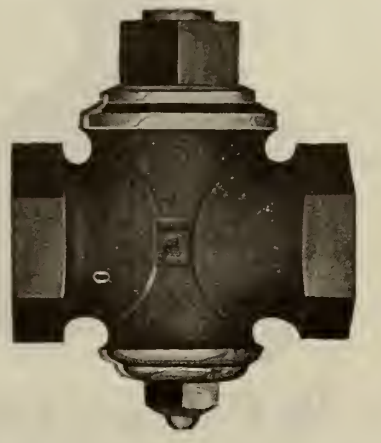
Ruin to the whole Steam System.

The loss of money and time to the client.

And the loss of the client's confidence in the sanitary engineer who installed the system.

It is worse than folly to pass on inferior stop cocks when Empire Steam Stop Cocks are available—and Empire Steam Stop Cocks always are available.

The factory test of the Empire Manufacturing Co., and our guarantee is behind the engineer who installs our stop cocks. Remember our guarantee has never failed.



A square client deserves Empire Steam Stop Cocks—they are the quality of stop cocks he expects from a reliable sanitary engineer.

TALBOT

Contra-Flow Steam Boilers

(Equipped with Crude Oil Burners)

"Talbot" Boilers have these advantages:
They weigh only one-quarter as much as an ordinary boiler of equal H.P.
They take up only one-seventh as much space as the ordinary boiler.
They require no brickwork.
They burn **cheap fuel oil.**

Two 1000 H.P. boilers for immediate delivery from stock.

Tubes are easily replaced under reduced steam pressure.

Built in all sizes from 50 to 4000 H.P.

HOMESTEAD, PA.

"Now that Federal Restrictions Are Removed We Will Extend the Plant and Install the Jeffrey Improved Carrier."

"The war and consequent government supervision will have a tremendous influence on power plant operation. The entire industry readily fell in line with the U.S. Fuel Administration and many long-standing wastes were eliminated.

"Reconstruction activities will call for a vast amount of labor, both skilled and unskilled. Consequently, wages will continue high, so that mechanical equipment will be far more economical wherever it can be applied. War-time wages have caused our coal and ash-handling costs to climb almost out of sight.

"The JEFFREY Carrier, which is built in six sizes, will handle 30 to 160 tons of coal or ashes an hour for far less costs. The plant will be cleaner and more efficient and the men will be glad to be released from this disagreeable duty."

Catalog No. 210-4 describes completely the JEFFREY Carrier. Write TO-DAY for your copy.

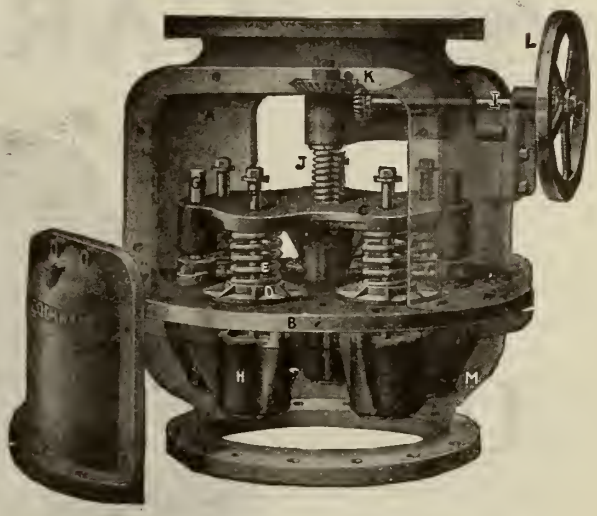
"DID YOU SEE IT AT BRANTFORD"

Some Pointers regarding the Cochrane Multiport

THE COCHRANE MULTIPORT

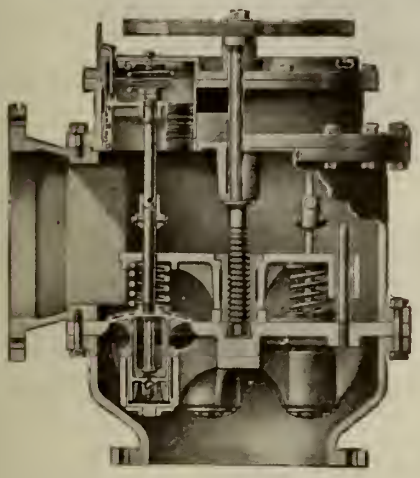
Is an improved Safety Valve
for the Exhaust Steam System

A UPPER CASING, having two removable doors, providing easy access to disks for regrinding, and to springs for removal, etc.
B VALVE PLATE, carries dash pots which guide and cushion the valves, and which are bored simultaneously with seats, insuring alignment.
C PRESSURE PLATE, motion limited to prevent exceeding a predetermined pressure.
D BRONZE VALVE DISKS. Cast integral with dash pot plungers.
E NICKEL-PLATED STEEL SPRING. Can be changed if a different back pressure is desired.
F BRASS LIFTING SPINDLES. Serve to lift disks off seats when exhausting free to atmosphere.
G BRASS SLEEVED GUIDE POSTS for pressure plate.
H DASH POTS. Bronze lining secured by nut on bottom.
I STEEL SHAFT for revolving bronze spindle; not required in horizontal form.
J BRONZE SPINDLE for raising and lowering pressure plate.
K BRONZE GEARS, not required in horizontal form.
L ADJUSTING HAND WHEEL. Valves are also arranged for control from distance by chains, extension shaft, hydraulic pressure, electric motor, etc.
M LOWER CASING.



Interior View, Fig. 1 000, Cochrane Multiport Safety Exhaust Outlet Valve.

WHEN used in back pressure service, it protects piping, radiators, feed water heaters, cooking kettles, absorption ice machines, low pressure turbines or other appliances, against abnormal rises in pressure whenever the amount of steam supply from the engine exceeds the ability of the exhaust system to condense or otherwise dispose of that steam.



Section of Cochrane Multiport Flow Valve for use in connection with Mixed Flow Turbine. Prevents condenser vacuum from backing up into the engine exhaust line and drawing in air through leaks, etc.

COCHRANE MULTIPORT VALVES for Vacuum Service are installed between engines or turbines and condensers. They serve not only to protect against abnormal rises in pressure, but they also provide a convenient and natural channel for the escape of steam during non-condensing operation. They are thoroughly water-sealed to prevent the entrance of air into condensers.

The main idea in designing the COCHRANE MULTIPORT has been to secure absolute safety by providing a number of channels of escape for the steam, so that the chances of all becoming inoperative at once are infinitesimal, at the same time doing away with the excessive list and severe hammering upon the seat inseparable from heavy single-disk valves.

In accomplishing this object, we have taken advantage of the opportunity to make the valve easily adjustable, that is, by varying the position of the pressure plate the tension of the springs may be adjusted for any back pressure desired. Where installed in connection with heating and drying system, it is thus often necessary to carry the maximum back pressure only for a few hours in the morning, while at other times the steam consumption of the engine is reduced by lowering the back pressure. With nearly all other valves, this is utterly impracticable.

The introduction of the pressure plate and spring principle into back pressure valve design also enables us to make the valves strictly foolproof, that is, it is impossible to overload or tamper with the valves, since the limited travel of the pressure plate determines the maximum back pressure. Inasmuch as there are no moving parts directly connected to the disks extending outside of the valve casing, overweighting, tying down or accidental obstruction are eliminated, likewise sticking through over-tightening of glands.

The method of control also makes it convenient to install appliances for operating the valves from a distance, as by means of a long shaft, a chain and sprocket wheel, hydraulic pressure, or by electric motor. That is, it is not necesasry to climb a ladder or to go up on the roof in order to change the back pressure, if you have a MULTIPORT. In atmospheric service, it is sometimes convenient to be able to open and close the valves from the switchboard, which can be arranged for with this type of valve.

In vacuum service, these valves offer perfect facilities for throwing over from non-condensing to condensing operation, especially in connection with reciprocating engines, since the engine may be allowed to exhaust through the valve until the moment when the main gate valve between the exhaust line and the condenser is opened, upon which the small disks will seat immediately without allowing an inrush of air thereby avoiding all danger of losing the vacuum and of having to prime the condenser over again. COCHRANE MULTIPORTS are built for all situations, that is, vertical pipes, horizontal pipes and angle pipes.

Special types of COCHRANE MULTIPORTS are supplied for preventing the vacuum from mixed flow turbines reaching back into the engine exhaust line, with consequent impairment of vacuum due to the drawing in of air through leaks in the engine exhaust piping, through piston rod packings, etc.

GARLOCK

PUMP VALVES

The service of pump valves depends upon the compounds as well as the consistency and cure of the valves. The compounds used in Garlock pump valves have been established after years of trial in actual service and under the most severe conditions. Pump valves should always be used for the purposes for which they are intended. The following are a few of our leading styles and grades of valves:

Style No. 139—For medium pressure cold water.
" " 175—For high pressure cold water.
" " 182—For warm or greasy water.
" " 108—For hot water.
" " 105—For boiling water.
" " 154—For air compressors and condensers.

We guarantee our pump valves to give satisfactory service when used under conditions for which they are intended.

"What *is* packing anyhow?"

Our salesmen frequently comment on how often their friends, outside the business, ask the question—"What is Packing?"

Some of the ideas as to the meaning of the word are very amusing in their vagueness and it is very seldom that the average man realizes just what a big part this product plays in the efficiency and economy of the industrial machinery that is making the world better for us all.

So for all its seeming insignificance the story of what packing is would seem to be well worth telling and well worth reading by anyone.

* * *

AS a starter, consider Packing as something like the "washer" in your kitchen faucet. It prevents leakage—or ought to.

Now whenever steam is put to work—or water, gas, brine, or ammonia—packing is needed. It is needed to prevent leakage where gleaming rods slide smoothly in and out of cylinders, for leakage here means not only loss of steam or water, but actual waste of power.

And inside the cylinders of pumps, packing again saves power. With perhaps two hundred pounds pressure on one side of the piston, and a vacuum on the other, piston packing prevents leakage past the piston.

And sheet packing, cut or molded into gaskets, prevents leakage at joints of surfaces or piping.

So, fundamentally, packing guards against leakage.

But when it works against moving surfaces, packing is subject to wear—or it goes "dead," and loses its elasticity. This means replacement, shut down machinery and expense. So the buyer of packing must ask not only "Will it prevent leakage?" but also "How long will it last?"—which of course depends on the material and workmanship put into it.

And there's a third question, which the engineer will ask if you don't, "How much friction does it cause?" For some packings prevent leakage merely by filling up the packing space as solidly as possible. Naturally such packing binds the moving rod—sometimes even scores it—and acts more or less as a brake. It is such serious faults as this that Johns-Manville has overcome through intelligent packing design.

So packing is not a thing to be bought at random — the right choice will save money by preventing leakage, by conserving power, and by its longer life.

As the pioneers in packing development we have placed packing design on a scientific basis, and out of experience, observation and facts have established a complete and standardized line that meets every plant requirement from among the minimum number of packings. Only in this way can packing be made to give a maximum of service for a minimum of cost.

Here is a partial list of Johns-Manville Packings: Sea Rings for outside packed Rods; Service Sheet, an all-around-the-plant sheet packing; Universal Piston for inside packed pumps; Kearsarge boiler, man and handhole gaskets; Mogul Coil Packing for valve stems and small rods; Sirgelite Sheet for packing oils, gasoline and naphtha.

REGISTERED COPPUS U.S. PAT. OFFICE

In Glass Works

In th Glass Dirisi-n Power Plant of the National Lamp Works out in Cleveland, Ohio, they burn gas coal screenings and producer tar—difficult fuel to burn economically. Yet with the 4-18" COPPUS Turbo Blowers which they operate, full steam pressure is maintained in their 4-250 H.P. Stirling Boilers—and cheap fuel is efficiently burned. Without these Blowers, one of which is shown above, additional boilers would have been necessary last fall. With their aid, however, the heavy plant load is easily handled.

Before the National Lamp Works installed COPPUS Blowers a careful investigation satisfied them that for efficient operation, low steam consumption, and sturdy dependability, COPPUS Blowers stand in a class by themselves. And after practical proof that COPPUS Blowers are all that is claimed for them, Mr. Bretz, Plant Superintendent, expresses himself as "highly pleased with them." In the National Lamp Works, as in thousands of plants in every industry, COPPUS Blowers have proved profitable investments.

Why not find out exactly how and why *"COPPUS Equipment can save you money."* Write us and our engineers will help you solve your combustion problems. If you haven't a copy of Blower Catalog H12, write for one to-day.

"We Prefer Nonpareil Corkboard"

Row creom storoge room, insuloted with Nonpareil Corkboord in the Pottstown, Pa., plant of Burdon Bros.

Burdan Bros., of Pottstown, Pa., have been in business for a good many years. During that time they have tried out a number of insulating materials. But what their experience has taught them is best told by Mr. C. C. Burdan in his letter of November 25, 1918:

"We have had considerable experience with various materials, also corkboard, for cold storage insulating purposes, and our experience has been such that we prefer Nonpareil Corkboard to any other form of insulation. In fact, our experience with the other materials has been such that **we would prefer Nonpareil even if it cost ten or fifteen times as much.** We cannot speak too highly of the Nonpareil Corkboard as an insulator."

Testimony such as this makes it easy to understand why most of the up-to-date ice cream manufacturers, ice and cold storage men, and other users of refrigeration use

NONPAREIL CORKBOARD INSULATION
FOR COLD STORAGE ROOMS

They know that cheaper materials will not be economical of refrigeration or stand up under the hard service encountered in the average ice plant. They know, furthermore, that quality considered, Nonpareil Corkboard proves to be cheaper in the long run than anything else they can buy.

Why not investigate Nonpareil Corkboard? It will cost you nothing to get full information

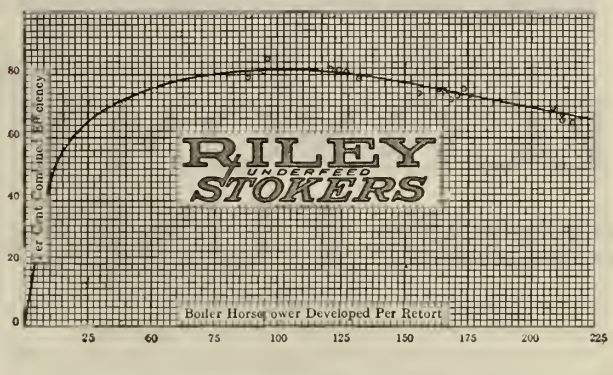
High Efficiency



The continuous high efficiency of the Riley Stoker is due to the moving grates. These moving units not only keep the fuel bed open, porous and free from clinkers, but automatically discharge the ash and refuse.

Because of the moving grates, Riley Stokers have that faculty of operating continuously at high efficiency and capacity. Fuel saving is a mechanical certainty. There can be no waste.

The efficiency curve shown above is typical of Riley Stoker performance. This curve is plotted from a series of tests conducted on a 16-retort Riley Stoker installed at the Essex Station of the Public Service Co. Why not duplicate these results in your plant? You can do it with Riley Stokers.

Making Templets for Machinery Foundations

Anchor Bolt Templets—Construction and Materials—Making Preliminary Drawings for Templets—General Procedure in Laying Out a Templet—Templet for a Corliss Engine Driven Generating Unit

By BRUCE PAGE

AN anchor bolt templet (Fig. 1) is a pattern or frame usually fabricated from wooden strips ⅞ in. thick, which is used as a guide for properly and accurately locating and sometimes for holding in position the anchor bolts or the anchor-bolt casings of a foundation, while the foundation is being built up around them. Where the anchor bolts are not equipped with casings, the templet then supports only the bolts, which pass through and are supported in holes bored in the templet as indicated in the illustrations. As indicated in Fig. 2, where the bolts are provided with casings, the templet supports and locates both the bolts and the casings. Nails can be driven in the bottom face of the templet to centre the casing around the bolt. Or bushings, such as nuts or pieces of pipe, can be dropped down over the bolts and within the casings, centering them.

Occasionally, as suggested in the following paragraphs, templets are used merely as guides to indicate the locations of the anchor bolts, and do not support either bolts or casings.

Classes of templets as to methods of construction may be divided into: (a) One-section frame templets; (b) Multi-section frame templets, and (c) Built-up templets. A one-section templet is one that is complete in one piece. This does not mean that it is composed of one piece of plank, but means that several pieces of plank are fabricated to form the templet unit. Multi-section templets are those which comprise two or more sections or units. Frequently the templet required for a given foundation is so large that it cannot be readily constructed or handled in one piece and then it must be made in sections.

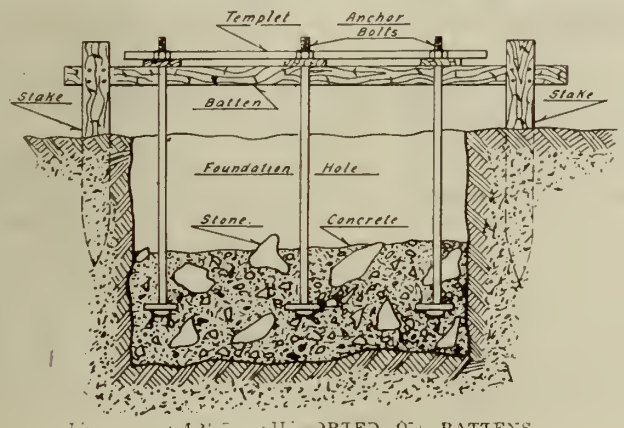

FIG. 1—TEMPLET SUPPORTED ON BATTENS.

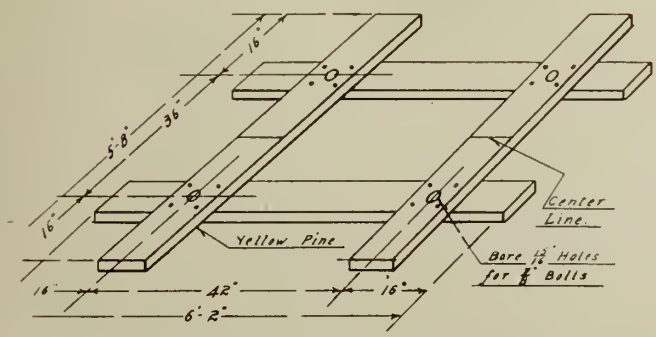

FIG. 3—TEMPLET FOR MOTOR BED PLATE.

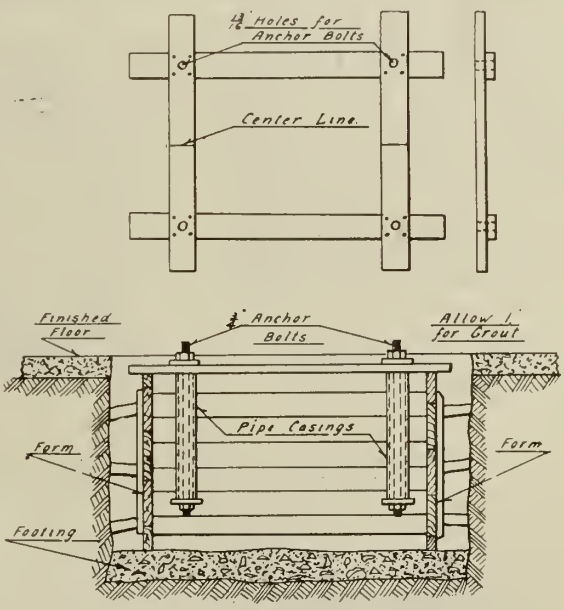

FIG. 2—TEMPLET AND FORM IN POSITION.

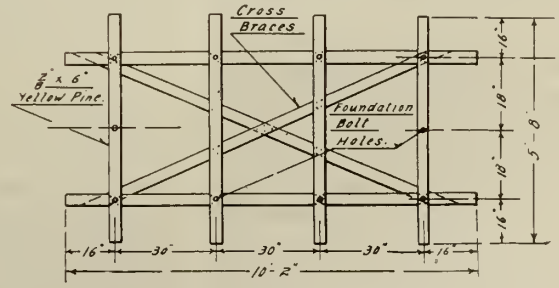

FIG. 5—ILLUSTRATING METHOD OF BRACING A TEMPLET.

Built-up templets are those that are not fabricated in the shop, but which are built up piece by piece over the foundation, the bolts of which the templet is to locate. Templets of each of these types are discussed in the paragraphs which follow.

It always pays to use a templet, even for the smallest foundations. It will practically always be found more economical to build a templet which will accurately locate the bolts in a foundation than to endeavor to locate the bolts without this guide. The templet can be made under conditions which conduce towards accuracy, and by workmen who are accustomed to making accurate measurements. But if the constructor endeavors to have the anchor bolts located "on the job" the locating will be done by masons or concrete men, and usually under adverse conditions, when close measurements are difficult to make.

The material for templets is wood or structural steel. Wood is by far the most frequently applied material because it is easy to work, and can be obtained in any community without delay. Templets fabricated from structural steel are used, particularly where the same templet is to be used repeatedly.

Wood templets are made of planks usually ⅞ in. thick, but they may be of any reasonable thickness. Almost any kind of wood can be used for making a templet, but because it is probably cheapest in the long run, reasonably clear-grained white pine (pattern wood) is most frequently used. Yellow pine, although it is heavy, makes good templets. Woods which tend to warp and distort should be avoided. As a rule the sticks composing the templet should be planed smooth on all four sides. Sometimes the sticks are planed on two faces only. For the roughest, simplest work, planing may be omitted altogether, and the rough planks used just as they come from the mill.

Steel templets are fabricated from angle or channel sections. When the templet is small, the component pieces of the templet may be held together with rivets. Where the templet is large, the pieces may be bolted together or the templet may be subdivided into riveted sections, each small enough to be readily handled, and then these sections can be bolted together to form the complete templet.

Templet drawings should be made for all except the simplest foundations. Such a drawing should be furnished the man who is to build the templet. The templet drawing (Fig. 3 shows a simple example) should indicate the length and location of each stick and the diameters of all the holes. All of the dimensions that are required for the construction of the templet should be shown. From such a drawing the carpenter can work without having to consult the foundation drawings for his dimensions and without having to make computations for himself in order to ascertain dimensions. It is certainly more economical to make in the drafting room a templet drawing having recorded on it all dimensions, than it is to render it necessary for the wood-worker to ferret out for himself the required dimensions from the machine or foundation drawing.

Templet construction is a very broad subject, hence in this article it is possible to suggest only general directions. Obviously a templet must be accurately

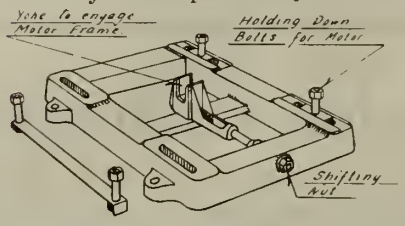

FIG. 4—BED PLATE FOR ELECTRIC MOTOR.

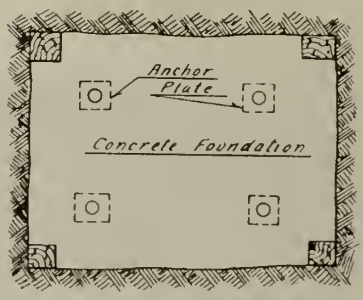

FIG. 12—PLAN OF FOUNDATION WITH POSTS EMBEDDED.

made so that the positions of the anchor bolts located by it will correspond exactly to the positions of the holes, for the accommodation of the anchor bolts, in the bed-plate of the machine. Templets may be of many different forms to accommodate different anchor-bolt arrangements. They should be composed of the fewest possible number of sticks and should be light in weight and yet substantial and rigid. The component sticks of a wooden templet are held together with flat-head wood screws, or in rough work, with clinched nails.

The general procedure in laying out a templet is about as follows: First, the principal centre line of the machine or foundation is marked with a chalk line or pencil on a smooth floor (Fig. 8) of sufficient area to accommodate the complete templet. Then the transverse centre lines are laid out in accurate relation, usually at right angles to the main centre line. Then the other minor centre lines are marked on the floor and the positions of the various foundation bolts located. Where an engine requiring dash pots is to be installed the locations of these should be indicated so that the templet can provide for their location. It is always well to show the centre line of the driving pulley or gear of the machine, if it has one, because the templet must often be located in some definite relation to some other machine or driving gear or pulley which may drive or be driven by the machine to be installed.

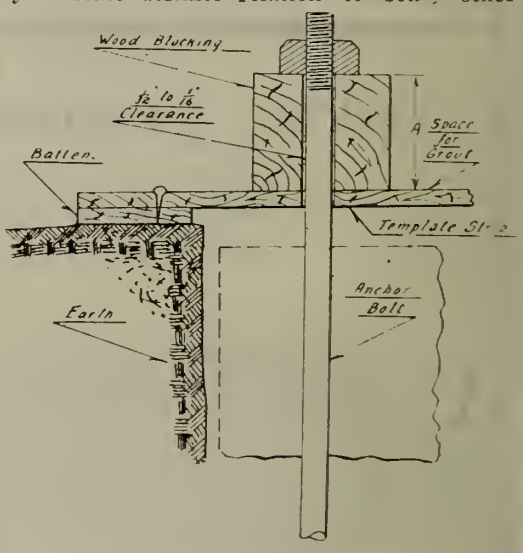

FIG. 14—ILLUSTRATING METHOD OF HOLDING UP BOLTS.

The centre lines and bolt locations drawn on a floor for a templet are shown in Fig. 8. After the centre line layout just described is completed, the pieces of plank which will be used to form the templet are fabricated over it. The layout on the floor really serves only to give the workman a general idea as to the locations that the different planks composing the templet should assume, one plank being laid centrally over the centre line and there nailed.

FIG. 8—CENTRE LINES LAID OUT ON FLOOR.

The bolt holes through the templet planks must be accurately located before they are bored, inasmuch as it is, of course, impossible to transfer their locations from the floor surface to the upper surface of the templet.

The diameters of the bolt holes through a templet should be such that there will be just enough clearance between the sides of the hole and bolt that it is to accommodate, so that the bolt will enter readily. For small bolts, pos-

sibly those of ¾ in. in diameter and less, 1-32 in. diametrical clearance is usually considered ample. That is, the diameter of the bolt hole through the templet should, for these small bolts, be 1-32 in. greater than the diameter of the bolt. For larger bolts a diametrical clearance of 1-16 in. is permissible.

Important centre lines should always show on a templet (see Fig. 3) so that they may be used in locating the templet in correct relation to the building or to existing machinery, line shafts and the like. Some erectors always arrange their templets so that a planed edge of a plank coincides with each important centre line of the templet. It is also frequent practice to use a line drawn down the middle of a plank with a scribe or a pencil as a centre line, but this method has the disadvantage that the line may sometimes become obliterated.

The construction of a 4-bolt templet for the foundation for the motor bedplate of Fig. 4, is shown in Fig. 3. For this templet, four pieces of 4 in. by 7/8 in. yellow pine, planed on four faces, were used. To hold the motor bedplate, four 7/8 in. diameter bolts were required, hence four 15-16 in. holes were bored through the templet in the locations indicated, for the accommodation of these bolts. Each of the four strips was made long enough to extend 14 in. beyond the edge of the cross-piece to which it was nailed to provide for its support on a form or battens as shown in Figs. 1 and 2 respectively.

Bracing is Necessary in Large Templets To Prevent Distortion

An example of such transverse bracing as applied to an 8-bolt templet is shown in Fig. 5. This templet is of relatively great length (10 ft. 2 in.) and it is apparent that if bracing were not provided there would be a possibility of the templet swinging out of shape and disturbing its accuracy. Examples of bracing on larger and more complicated foundation templets are shown in other illustrations.

A templet for a Corliss engine-driven generating unit (Fig. 6) is shown in Fig. 7. This unit, Fig. 6, comprises a 20 in. by 36 in. 150 r.p.m. engine direct-connected to a 375 kva. 240-volt generator. The foundation drawing and the bolt layout from which the templet drawing was made are shown in Fig. 6. Fig. 8 shows the centre line layout on the floor of the pattern shop. Over this layout the templet of Fig. 7 was constructed. Note that this templet is thoroughly braced to prevent any possibility of distortion. Note also that blocks (see Fig. 14) must be nailed on the templet strips at certain locations so that the upper ends of the foundation bolts will all lie at the correct height. Certain of the strips comprising the templet have been made long enough to extend considerably beyond its actual outline to provide for the support of the templet on the form for the foundation. This templet was made in two sections. One section, B, is designed to carry the anchor bolts for the engine proper, while section A is designed to carry the anchor bolts for the generator and for the outboard bearing. Had this templet been made in one section it would have been so large as to be unwieldy.

The construction of a templet for a machine having elevated outboard bearing is shown in Fig. 9. The foundation, with the anchor bolts in position, for which this templet was used, is delineated in Fig. 10. The elevation of the portion of the foundation, which carries the outboard bearing above the balance of the foundation, involves rather complicated templet construction, as suggested in Fig. 9. The portion of the templet supporting the outboard-bearing bolts is held on 2 in. by 4 in. struts, to which are nailed 1 in. by 6 in. ledgers or cross-pieces. Two 2 in. by 6 in. timbers extend across both of the long strips of the main portion of the templet and out past the outboard-bearing part, acting there as cantilever beams. To prevent any possibility of these 2 in. by 6 in. beams tilting, stay blocks (Fig. 9, III) are nailed on each side of the beams to the main templet strips.

The construction of a templet in the field usually involves the use of a transit. Templets for very large foundations, possibly 60 ft. to 100 ft. or more long for rolling mills or other large machines, are sometimes built in this way, In building such a templet the carpenters work under the direction of an engineer, who operates the transit. The engineer locates the foundation bolt points by referring to the foundation drawing of the machine. The stringers are first laid and fixed solidly in position, Fig. 11, and then the templet is built piece by piece by fastening the planks to the stringers in the right positions and boring therein the foundation bolt holes at the proper points. The points of locations of the holes are determined by the engineer and his assistants.

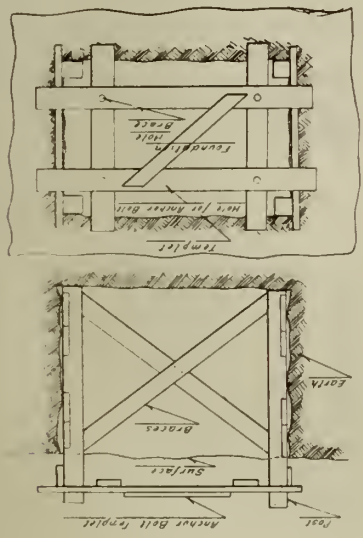

FIG. 9 TEMPLET FOR ANCHOR BOLTS OF FOUNDATION.

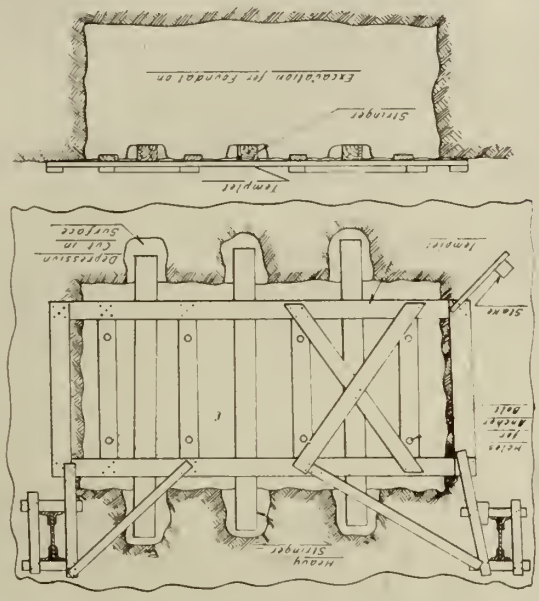

FIG. 11—ONE METHOD OF SUPPORTING A LARGE TEMPLET.

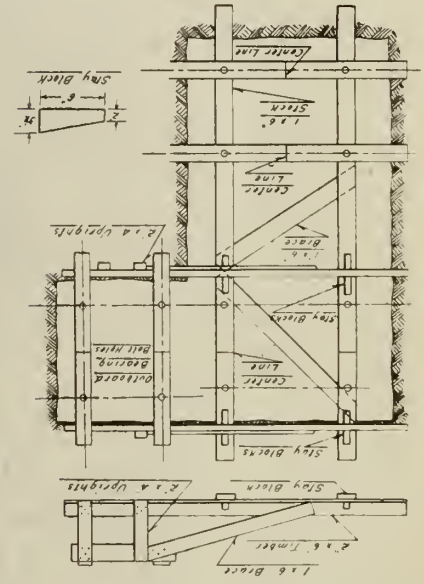

FIG. 13—TEMPLET SUPPORTED ON A FORM.

As to methods of support, there are two general classes of templets: (a) suspended templets; (b) subvened templets. Each of these methods will be discussed in detail in the paragraphs that follow.

Suspended templets are those that are supported from overhead, from the roof trusses or the floor beams of a structure or from an overhead framework erected especially to support them. Suspended templets are located high enough about the elevation of the top of the finished foundation so that men can walk under them and so that the concrete or other foundation materials may be handled below them without interference. They are frequently used for rolling mills and similar complicated foundations that cover large areas and contain many anchor bolts. A suspended templet is usually merely a frame mounted overhead with the location of every anchor bolt that is to be placed under it indicated on

its lower face by some kind of a mark. In locating an anchor bolt a plumb bob is temporarily dropped down from each one of these marks until the corresponding anchor plate has been set and secured in position at the point indicated by the plumb bob. The anchor plate then locates the bolt. Suspended templets will not, except in a general way, be treated further in this article.

Subvened templets are those that are supported from below, that is, they rest on their supports, as shown in Figs. 1 and 2. Subvened templets are sometimes called "dependent" templets, but subvened is a better word, inasmuch as dependent carries with it merely the idea of being supported, hence a dependent templet may be supported from either above or below. Subvened templets are used much more frequently than suspended templets because the subvened type can be effectively applied for all ordinary detached foundations such as those for engines, electric generators and motors, metal-working machinery and the like.

The methods of supporting subvened templets are many. Several typical ones will be described in following paragraphs. Whatever supporting arrangement is used it must be substantial and placed at such an elevation that the bolts will be maintained firmly and accurately in the locations that they are to occupy in the completed foundation. Templets may be supported on the forms of concrete foundations as diagrammed in Fig. 2. The form for the foundation is usually made of such a height that its top lies at the same elevation as that of the top of the finished foundation. The templet can be designed that its lower edge should rest on the top of this form. Inasmuch as the form should be carefully levelled and approximately aligned before any concrete is poured into it. This constitutes an ideal arrangement for holding up a templet.

Battens are used for supporting templets, for masonry foundations or for concrete foundations where no form is used (Fig. 1). Frequently the earth in which the excavation for the foundation is made is sufficiently solid that it is self-supporting, in which case the sides of the foundation hole constitute the form. The battens are nailed to pointed stakes, which are driven into the ground. Four stakes and two battens suffice for a small foundation, but a number of stakes and four battens, one on each of the sides of the foundation, should be used in the more important installations. This method is effective and inexpensive and finds frequent application for small foundations.

A method of supporting templets on stringers fastened on posts set in the corners of a foundation hole is shown in Figs. 12 and 13. This method is used only for foundations for which forms are not required. It can be applied for either masonry or concrete foundations. Four posts, one in each corner of the foundation excavation, are driven into the earth as suggested in Fig. 12. The size of the posts used is determined to a certain extent by the weight of the templet to be supported. Ordinarily, nothing smaller than a 4 in. by 4 in. post is used, and 8 in. by 8 in. sticks are none too heavy to ensure the stability of a large templet. The posts are held vertically in position by side and cross braces as shown in the sectional elevation of Fig. 13. The level at which the bolts are to be set having been determined, battens of suitable size, usually of 1 in. stuff, are nailed to the uprights. For a small foundation, two battens arranged as shown in the plan view of Fig. 13 are ample, but for large foundations four battens, one along each of the form edges of the foundation should be used. The battens are set at such an elevation that when the templet is placed upon them and the anchor bolts inserted, the bolts will be at the proper level. The hole is filled with concrete. After the concrete has set, the templet can be removed. The uprights or posts

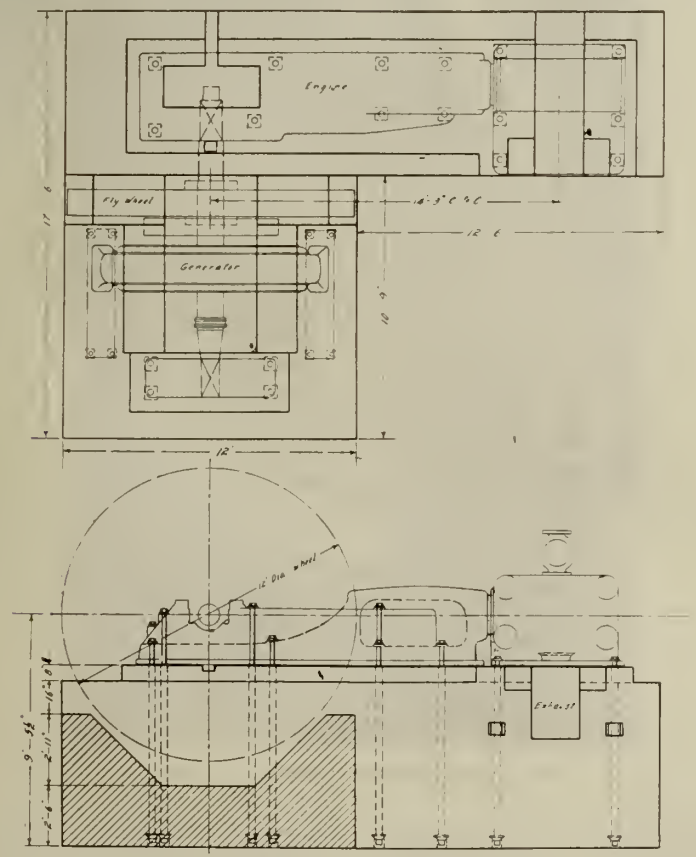
FIG. 7—TEMPLETS FOR LEFT HAND, 150 R.P.M. CORLISS ENGINE-DRIVEN GENERATOR.

are then sawed off flush with the foundation top. The balance of the wood is permitted to remain in the hole, the plan view of the completed foundation then being as shown in Fig. 12.

The method of supporting a templet on stringers is shown in Fig. 11. This arrangement may be effectively used for the very largest foundation. Heavy timber stringers laid across the foundation hole with their ends resting in depressions of such depth that the lower face of the templet will, when it rests on the stringers, be at the elevation of the top face of the foundation. The stringers support the templet, which in turn carries the anchor bolts. Where the anchor bolts are quite large, possibly 2 in. in diameter, their weight will be considerable, and the stringers must be so disposed that the templet, which is usually of relatively light stock, will not be subjected to excessive stresses. When the bolts are heavy the stringers should be located near the rows of bolt holes rather than midway between them as shown in Fig. 11. Where a templet is to be supported as suggested in Fig. 11, it may, unless too large, be built complete in the carpenter or pattern shop. It



FOUNDATION FOR CORLISS ENGINE.

can then be transported to the foundation hole and located accurately on the stringers.

Templets built up in the field can frequently be used to advantage, although for the ordinary foundation it is believed that the most economical procedure is to build the templet in the shop. The process of fabricating a templet in the field is as follows:

The excavation for the foundation having been complete and the footing course being in position, the exact elevation of the completed foundation top is determined. The principal centre lines of the foundation are also determined and each designated by marks on the floor, or by tight cords or wires. Then heavy timbers are laid across the foundation excavation, somewhat as suggested in Fig. 11. Ordinarily 2 in. by 6 in. or 2 in. by 8 in. timbers are sufficiently strong, and they should be set on edge like the beams of a floor. They should be arranged 24 in. to 30 in. between centres, and their top edges should lie ⅞ in. (to allow for grout) below the elevation of the finished foundation top. Cross bridges should be nailed to the tops of these timbers to retain them securely in their positions.

The beams are then overlaid along the lines where the anchor bolts are to be suspended, with ⅞ in. by 6 in. strips which are nailed to the beams. The beams must be so located that they will not interfere with the bolts. If certain bolts are to extend to a higher elevation than others they should be blocked up as suggested in Fig. 14. The exact centre lines of all of the bolts are laid out on these ⅞ in. strips. At the location of each bolt a hole is bored through the strip large enough to accommodate the anchor bolt with the clearance suggested above. Now each anchor bolt is hung in position in the templet and a wooden block of a thickness of the bed-plate (A, Fig. 14) is inserted over the head of each bolt. Then the nut on the upper end of the bolt is screwed down to the position that it should assume when the foundation is completed and the bed-plate in position. In thus setting the bolts, allowance should be made for the grout that should be poured between the bed-plate and the top surface of the foundation. After the foundation has been completed the timbers are removed.

The method of blocking up anchor bolts that they will lie at their correct elevations is shown in Fig. 14. Blocks of wood, each with a hole bored through it, short lengths of pipe or piles of washers or nuts that will slip over the end of the bolt can be used for this blocking.

TESTING OUT CIRCUITS BY MEANS OF A BELL

In testing out electric circuits about a gasoline engine and to see if they are broken or not I often use a common door bell with two copper coins, each having a hole in the centre of it, placed one on each terminal of the bell. To test if the central electrode of a spark plug is broken connect its terminal to a dry cell and connect the remaining terminal of the cell and the inner end of the spark plug electrode through the bell. This can be done by bringing the spark plug close enough to the cell that each can be put into contact with one of the coins on the bell, each touching a different coin. If desired a wire may be hooked onto one bell terminal along with the coin as the parts are generally long enough to allow this. Conductors may each be tested out in this way also. If the bell rings current is flowing. Do not attempt to connect the bell into the high tension circuit with the high tension current on it at the same time. One dry cell is generally current enough for testing for broken circuits. When uncertain which of two or more ends is the second end of a given conductor connection of the cell to the given wire and to the bell and touching the other bell terminal to each of the doubtful ends in turn will decide the question, for the bell will ring when the right end is tried. Canadian copper coins on the bell terminals wil reduce the distance between enough that the bell may be used to test and enable one to approximately judge of the strength of dry cells if the ammeter is not within easy access. Touch the cells as with an ammeter and hear how loud the bell rings but do not leave the bell ringing very long as one could weaken the cell some that way in a little while, there being no line resistance to reduce the amperage.

J. E. McCORMACK.

To Settle Dispute.—The Nova Scotia Legislature is about to introduce a bill to force the Dominion Coal Co. and the Nova Scotia Steel and Coal Co. to settle their differences. This will be done by compelling the companies to submit to a re-arrangement of their leases, which will allocate all the areas north of Sydney Harbor to the Scotia, and all those south of Sydney Harbor to the Dominion Co.

Methods of Guarding Engines and Turbines

The "Travellers Standard" Has Some Interesting Information on Different Forms of Safety Apparatus as Applied to Governors, Fly Wheels, and Rotors.

IT is often assumed that the stationary engineer has an easy job, and that his main duties consist in starting and stopping the engine at the beginning and end of the working shifts, while in the meantime he sits in a comfortable chair, smokes his pipe, and reads the nswspaper. Even the owners of power plants appear to hold this opinion in some cases, and in order to put "spare time" of engineer to profitable use they make him a sort of general factotum. The position calls for efficiency in various mechanical lines, and when some trifling job has to be done it is perhaps natural to wish it upon the engineer, because in all probability he will know just how to do it. To a certain limited extent this is all right, but the thing can easily be overdone. For example, the engineer should never be required to go to some other part of the shop or factory to repair a disabled machine or set up a new one, or to change over or add to a piping system, mend a broken belt, or do any of the other countless odd jobs that constantly require attention, in every manufacturing plant. When service of this kind is required of him, the engine is often left wholly unattended in the meantime, or perhaps the fireman or some other less qualified person is told to "keep an eye on things." A plant operated on this basis is in constant danger, because at any moment conditions may arise that will lead to a bad accident. The engine should never be left unattended, and if it is necessary for the engineer to be absent from the engine-room temporarily, some person known to be competent and trustworthy, and capable of doing the right thing in time of emergency, should be delegated to take his place.

The position of stationary engineer is an exceedingly responsible one, which calls for a high-grade, versatile man, having a broad general knowledge combined with a large amount of manual skill. He must also have had thorough training and considerable experience so that he can not only diagnose engine troubles quickly and accurately, but also superintend the work of making such repairs and adjustments as the engine may require.

The employment of a first-class engineer is the prime requisite for securing safety, but various other matters must also receive attention if the plant is to be properly protected and some of these are mentioned in the following paragraphs.

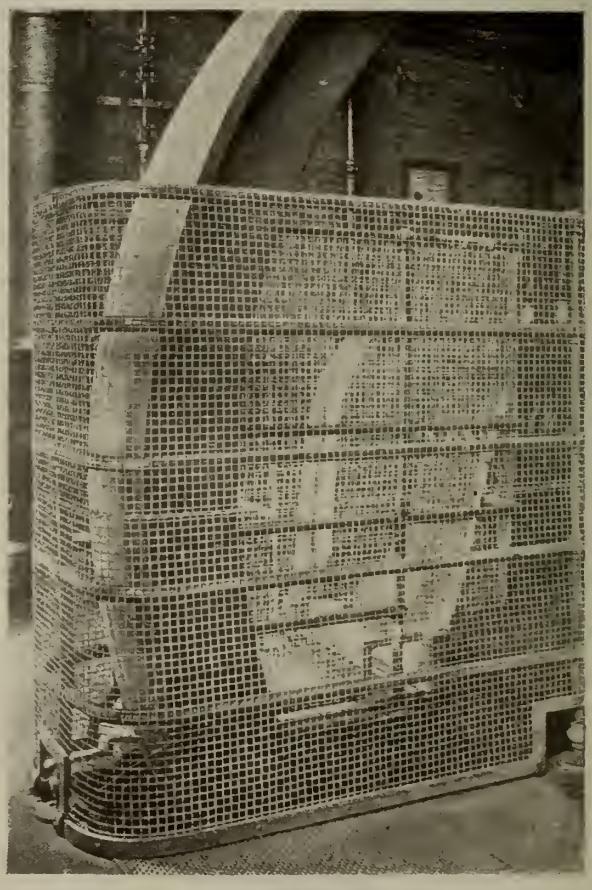
Of the more serious accidents that occur in conection with steam engines, those due to bursting flywheels are doubtless the worst, and perhaps they are also the commonest. The principal causes of flywheel explosions are excessive speed, sudden and extreme variations in the load, and defects in the wheels.

A sudden increase in the load on an engine may produce exceedingly heavy stresses in the flywheel, particularly when the wheel is merely used for steadying the motion of the engine by the storage of momentum (or of kinetic energy), and not for carrying the driving belt. The momentum of the rim in such a case tends to produce severe stresses in the spokes and the hub, and fracture may result unless the wheel is designed for this type of service, and is also in good physical condition every way. The flywheels of rolling mill engines are subject to extraordinarily heavy duty of this kind, and must be built with special reference to violent changes of speed.

Every flywheel, whether subjected to sudden variations of load or not, should be examined frequently and thoroughly, by expert inspectors, for the detection of weaknesses and defects, and the discovery of dangerous conditions associated with the operation of the engine, and immediate compliance should be accorded to the recommendations that are made in consequence of such examinations.

The speed at which a flywheel may be safely run depends upon the design of the wheel, the material of which it is constructed, and to some extent upon the conditions under which the engine is operated. The limit at which the speed ceases to be safe should be determined by the use of approved rules and formulae, and should never be exceeded, under any circumstances. A flywheel may be actually operating at a speed considerably below its maximum safe limit, but unless this fact is positively known, it is dangerous to increase the speed of the wheel without first considering carefully all the consequences of such action and calculating the additional stress that would be produced in the wheel by the proposed increase in speed. Lack of care in this matter may be followed by a disastrous explosion.

Comparatively few of the accidents that arise from excessive speed are caused by intentionally increasing the speed, however. Most of them are caused by the failure of the governing mechanism, or by a sudden fluctuation



PIPE RAIL GUARD WITH WIRE MESH.

from full load to no load (such as might be caused by the breaking of the main belt, or the failure of some of the main shafting, or the burning out of an armature if the engine is direct connected to an electric generator,) any one of which might cause the engine to race or run away.

Frequent examination of the entire governing mechanism is essential to make sure that it is in good working order. The belts of belt driven governors should be kept at the proper tension, and free from oil and grease which would cause them to slip. See, furthermore, that the key or set-screw that secures the governor pulley to its shaft is kept

GOOD GUARD FOR A FLY BALL GOVERNOR.

tight, and that the gears of gear-driven governors are in good condition. Provide suitable guards for the balls of fly-ball governors, particularly when they are located near oilers' walks or passageways of any kind. Basket-shaped guards, made of sheet metal or stout wire netting, are often used for this purpose. A good type is shown in Fig. 1.

A rope drive may be used for a governor in place of a belt drive, and it has many good features. It should preferably consist of two or three separate ropes, each strong enough to operate the governor alone. With an arrangement of this kind no harm can result in case one of the ropes breaks, and the ropes can be replaced one at a time as they become worn. In some plants, where the multiple-rope drive is used, a board or piece of sheet metal is secured in place close to the pulley over which the ropes pass. If a strand of one of the ropes breaks the flying ends will then strike the board of metal and call attention to the danger.

A positive stop should never be placed under the governor rod. When a governor rod stop is needed to facilitate starting the engine, an automatic device should be provided, which will drop out of the way as soon as the rod rises, and leave a clear path for the rod to descend to its lowest position.

A governor safety stop should be provided in connection with each fly-ball governor. This may be operated electrically or mechanically, and should be arranged so that when the governor rod descends to a dangerously low position (in consequence, for example, of the breaking of the governor belt,) a spring or some other equivalent device will be released, which will close the steam admission valve and stop the engine. Protection against over-speeding in case of the breakage of the governor belt may also be secured by using an idler pulley, which rests on the belt under ordinary circumstances, and is connected to a quick-closing valve in such a way that the steam will shut off if the belt breaks and allows the idler pulley to drop.

Automatic speed limit stops, designed to limit the speed of the engine independently, are often installed in addition to the governor, and the use of an approved device of this kind is strongly recommended; but even when it is provided no precaution should be omitted that would tend to insure the safety of the workmen and the equipment in case the automatic apparatus should fail to operate in an emergency. Some of these devices are more or less complicated in design and construction and require careful mechanical adjustment, and some of them operate by opening or closing an electrical circuit. They should receive proper care, and they should be tested frequently and regularly, to insure dependability. The character of the tests should be such as to leave no doubt with regard to the positive and effective operation of the apparatus. Frequent tests should also be made of the circuits (when electrically-operated devices are used), to make sure that there is always sufficient current to operate the mechanism effectively, and to discover possible short circuits and other electrical defects. Batteries (when they are used) should be renewed before they become too weak to furnish the needed current, and in all circuits the connections should be kept clean and tight. The wires should preferably run in conduits, but if that is not feasible they should be thoroughly insulated and effectively protected against moisture, grounding and short-circuiting.

It is important to provide the most complete protection to every part of the apparatus that serves to stop the engine automatically in case the speed should exceed the safe limit. If the apparatus is operated electrically, for example, the batteries and the conducting wires should always be located so that they cannot be damaged by a broken main driving belt, nor in consequence of any other accident that can be foreseen and which might precede or accompany the racing of the engine. This same caution applies to every other part of the apparatus that is concerned in the control of the speed, and to every method of control, whether electrical, mechanical or pneumatic. Many plants that are elaborately provided with independent engine stops show the greatest imaginable lack of forethought with respect to the protection of the apparatus against damage from the very causes that may lead the engine to run away; and a plant of this kind is poorly protected, in spite of the impressive array of mechanism that may be in evidence.

When automatic engine stops are used it is advisable to arrange them so that in case of accident they may be operated from any room or department in which power is used. This is a simple matter if the stop is of the electrically controlled type, because it is easy to run wires through the various rooms, and to install push-buttons at any number of convenient or important points; and even if the stop is not in itself actuated by electricity, a special control apparatus can readily be designed for operating it electrically from any part of the plant. Moreover, the exercise of a little ingenuity will enable one to devise simple mechanical controlling arrangements which will operate satisfactorily from points not too far remote from the engine room. Flexible wire cords passing over pulleys may often be used with advantage for this purpose. In addition to such devices, and particularly in large plants, we recommend that independent electric signalling systems be provided, to facilitate quick communication between the engine room and each of the various departments.
